Another child were born at present it could only be at the expense of those already finding life and health precarious. An increase in grain imports would not help this family, who cannot afford even to draw their full ration (10 oz. or 280 g. rice per head per day—1,000 calories approx.).

In January, 1945, I did a survey of health and diet of five families earning Rs.18 per month. I found that two families, consisting of two adults only, were getting 1,700 and 2,100 calories per intake unit. Those with children were getting 1,200 to 1,400 calories per intake unit (Stiebling scale). Protein varied from 23 to 40 g. per day and calcium 0.08 to 0.2 g. (standard requirement 0.6 g.). In both cases the intake was lowest where it was most needed, in families of growing children. Health varied correspondingly. These are the facts, a problem for those who have to face them in practice.

I agree with Dr. Kirman that this situation cannot be remedied "by efforts on the part of Europeans—no matter how well meaning—to alter the marital habits of the Indian peasant." My plea is this, that there should be made available for poor parents who care for the well-being of their children the knowledge that at one part of the menstrual cycle only is conception likely to occur, and that if they abstain from intercourse during that period they may be able to avoid further undermining the health of the children they already have by annual additions to the family. This knowledge will become available for such people only in so far as it is absorbed into local lore

and tradition. It cannot be forced on them by foreigners. I believe, however, it would be readily accepted and applied by them if all Indian doctors, especially women, and welfare workers who really care about them told them the facts.—am, etc.,

Travancore.

(Mrs.) A. W. MEGAW BROWN.

Obituary

Dr. CRAWFORD SMITH CRICHTON died suddenly at his residence in Redhill, Surrey, on July 20, aged 64. He was the son of J. S. Crichton, M.D., of Arbroath, and was born in that town. From the Arbroath Academy he went to Edinburgh University, where he qualified M.B., Ch.B. in 1903. After graduation he acted as house-surgeon at Noble's Hospital in the Isle of Man, and was later assistant medical officer at Bexley Asylum. He then assisted Dr. Spencer Palmer at Redhill, whom he succeeded in 1912. During the war of 1914–18 Dr. Crichton served in the R.A.M.C. on the Western Front; being sent home in 1917 as surgeon to the Redhill War Hospital. He was subsequently medical officer to the Poo Law Infirmary at Redhill, and when this became the County Hospital he was appointed visiting surgeon, a post which he held at his death. He was also senior surgeon to the East Surrey Hospital, medical officer to the St. Anne's Institution and district medical officer for Redhill.

Dr. Crichton was a man of strong personality, unlimited energy, and great administrative capacity. These qualities were combined with great clinical ability, and it is not surprising that he held the highest posts and had enjoyed most of the honours open to a medical man in his district. He had been chairman of the medical staff of the East Surrey Hospital for some years, a former chairman of the Reigate Division of the B.M.A., and a past president of the Surrey Branch. He was president of the Surrey Medical Benevolent Society and a member of the Surrey Hospitals Divisional Council. It is only his passing which has brought full realization of the scope and quality of his activities. A fine surgeon, he was a brilliant example of the general practitioner who has developed specialist interests, a leader in all professional affairs, and an outspoken opponent of all encroachments on professional liberties. His loss will be keenly felt both by the profession and the public.

K. W.

Dr. JOHN ALEXANDER WILSON died suddenly on July 30. He qualified M.B., Ch.B. Glasgow in 1909. His service in the Glasgow Public Health Department goes back to the second decade of the century, when he was transferred from the central laboratory to the tuberculosis service, then in its infancy. He was awarded the O.B.E. in the first world war for the laboratory work he did in association with the late Sir John Rose Bradford. In 1929 he was appointed Physician-Superintendent of Glasgow's new hospital for children at Mearns Kirk. He also became the senior lecturer on clinical tuberculosis at Glasgow University. At Mearns Kirk, Dr. Wilson combined the functions of physician and administrator with marked success. At the beginning of the recent war the hospital was more than doubled in size to about 1,200 beds for the treatment of naval sick and wounded.

Sir Alexander Macgregor writes: I know of no man of whom it can be said with greater truth that his work was his life. He loved his hospital and everyone in it; he was rewarded by the deep affection and esteem of staff and patients alike. His happy disposition made him a popular figure, especially with his child patients. As a superintendent he was friendly and accessible, his success being in large degree due to the high personal standard of work and conduct he set for himself, which acted as a stimulus and example. He never lost his scientific outlook. His interest in bacteriology, which was his first love, led him to spend most of his spare time in the hospital laboratory, investigating, among other subjects, the incidence of human and bovine tuberculosis, and preparing a remarkable series of pathological specimens for teaching purposes. He knew the art of clinical instruction, and his bedside demonstrations were enriched by his wealth of experience and enlivened by his keen sense of humour. In spite of a lingering illness, he carried on, brave, kind, and thoughtful for others to the end.

HERBERT HARLAND RAW, one of the best-known local medical men, died at Whitby, Yorkshire, on Aug. 5 at the age of 68. He was the son of the late Rev. John Frank Raw, of Danby, and through his mother was first cousin to the late Sir Stanley Woodwark, F.R.C.P., and the late Dr. C. S. Woodwark, of Grimston. He was a student contemporary of both his cousins

St. Bartholomew's Hospital, and qualified M.R.C.S., L.R.C.P. in 1901. Almost immediately after qualification he settled in practice at Whitby, where his mother and most of his ancestors had been born. He became in time almost, but not quite, the ozen of the local profession. He was medical officer to the post Office, to Trinity House, and to the Whitby Institution, local police surgeon, and honorary surgeon to the cottage hospital. During the first world war he served with the R.A.M.C. for our years, mostly on hospital ships but also in Mesopotamia and Persia. In Whitby he will long be remembered for his interest in local affairs and his successful efforts in connexion with housing schemes and public health. He was elected to the urban council in 1922, and served as chairman in 1926; during his membership he did much for maternity and child-welfare. For ten years he was divisional surgeon to the local St. John's Ambulance Brigade. Some years ago he was joined as junior partner by Dr. R. N. P. Wilson, and later by Dr. Cedric Cone. On his retirement in July, 1945, after prolonged ill-health, he resided at Captain Cook's house in Grape Lane, Whitby, which he had purchased some years previously. Dr. Raw is survived by his widow, two sons, and one daughter. He had been a member of the British Medical Association for many years and in 1936 was chairman of the Scarborough Division.

VERNON THORNE THORNE, born in 1904, was the son of Dr. Richard Thorne Thorne and grandson of Sir Richard Thorne (Thorne, K.C.B., F.R.S., F.R.C.P., both of Bart's and the latter on the teaching staff of the hospital. Educated at Marlborough and Caius College, Cambridge, he entered Bart's in 1926 and took the M.R.C.S., L.R.C.P. in 1930. He graduated M.B., B.Ch. two years later and joined his father in general practice at Woking. After three years he decided to join the Colonial Medical Service and so he obtained the D.T.M.&H. in 1936 and chose Nigeria as his colony. When the war broke out, failing to secure his release to join the R.A.M.C., he continued with his duties in Nigeria and the British Cameroons and worked exceedingly hard for long-extended tours of duty. He became seriously ill in March, 1945, and was invalided home in June of that year suffering from a tropical form of chronic endocarditis. After three months in hospital he returned to his home, where he died on August 5. He was married at St. Bartholomew's the Great in January, 1938, and leaves a widow and daughter.

On July 22 LUDOVICUS CORNELIUS JOSEPHUS BOECKX died in Fulham at the age of 71. He was born in September, 1874, at Antwerp, the seventh of the eight children of Louis and Coleta Faes. Educated at Malines, he studied medicine at Louvain University and graduated with distinction as M.D. in 1897. After filling a hospital appointment at Louvain he returned to Antwerp, where he served on the staff at St. Camille and St. Mary's Hospitals. When Antwerp fell to the invading German forces in 1914 he escaped to England, whither his wife and family had preceded him. At that time foreign refugee graduates were being admitted to the British Register without further ado, and Boeckx settled in London, where he had a practice in South Kensington and also consulting-rooms at Fulham. He never returned to practise in Belgium, having too clear an insight into German cruelty and mentality to risk a return to his native land; and events proved the prudence of this decision. Of recent years he worked in Fulham only, where he devoted much of his time to specializing in the treatment of venereal diseases. He only relinquished work quite lately, when overtaken by illness. He married, in 1900, Elizabeth Grange of Antwerp, who survives him with their two sons and two daughters, all of whom are married.

H. R.

By the sudden death at the age of 71 of ERNEST WARDLAW MILNE on Aug. 4 at New Barnet, the Barnet district lost one of its oldest active practitioners. Milne took his M.B., B.Ch.B. at Glasgow in 1900 and had practised in Barnet since 1906. From his early days he was intensely interested in ophthalmology and in later years this speciality took an increasing amount of his time. He served with the B.E.F. in 1916 and during the recent war with the Home Guard and on medical boards. Throughout his extraordinarily active life Milne succeeded in retaining a zest for keeping abreast of the latest work in medicine—and he combined this with a keen psychological insight and a determination to do all that he was physically capable of doing for the welfare of his patients. It is understandable, therefore, that he built up a large practice quite apart from his eye work. In his younger days he excelled at tennis, was a keen follower of Rugby football, and an enthusiastic fisherman—like the true Scotsman he was. Amateur theatricals at one time took such leisure as he had,

and in more recent years social welfare, in particular the religious side, attracted his deep and sincere interest. If one had to select one characteristic above all others it would not be his natural zest for life, his energy and sense of humour, nor his interest in all aspects of medicine, but his strong belief in the inherent goodness of the ordinary man. During twenty years' close association with him not one unkindly criticism of anyone can be remembered—albeit he had strong beliefs and never failed to express them clearly. Milne joined the B.M.A. in 1911 and was chairman of the Barnet Division in 1929. He leaves a son in practice and a married daughter, and the attendance at the funeral must have shown to his widow and family how widely loved he was in the district to whose interests he can be truly said to have given a life of service.

Medico-Legal

A HERBALIST FINED

The recent prosecution of Mr. Albert Lindley Payne, of Shipley, for pretending to be a registered medical practitioner has particular interest in view of the probability that the Medical Act, 1858, will be revised. Section 40 lays down that any person who shall wilfully and falsely pretend to be or take or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner or apothecary, or any name, title, addition or description implying that he is registered under the Act, or that he is recognized by law as a physician, or surgeon, or licentiate in medicine and surgery, or a practitioner in medicine, or an apothecary, shall upon summary conviction for any such offence pay a sum not exceeding twenty pounds. As the reported cases on the Section show, these words leave plenty of room for ambiguity and evasion, and the joint recommendations just published by the three defence societies (*Journal*, July 6, p. 21) ask that the forbidden designations should include abbreviations of recognized medical qualifications, the courtesy title of "Dr." when associated with the healing art, and any other common description generally accepted as indicating a registered practitioner.

Mr. Payne was summoned for using the letters M.B. implying that he was registered, also for issuing two certificates purporting to be medical certificates and carrying out two medical examinations, thereby implying that he was registered. The prosecution, instigated by the London and Counties Medical Protection Society, showed that Mr. Payne had displayed a placard outside his house describing him as a herbal practitioner. The word "medical" in front of "herbal" had been painted out—according to Mr. Payne some time ago; the placard also offered massage, manipulative surgery, and artificial sunlight. A woman witness said that she went to Mr. Payne's house and was ushered into a room full of medical instruments. She complained of being run down, and Mr. Payne examined her with a stethoscope, gave her some medicine to take three times a day, and wrote her a certificate signed with his name followed by the letters M.B. and some others that were indecipherable. An inquiry agent was next sent to the house, and Mr. Payne met him in a white coat. This witness said he had complained of a duodenal ulcer (this was true), and Mr. Payne, after examining him, also with a stethoscope, drew a sketch of the ulcer and gave him four bottles of medicine, three packets of powder, and a certificate of which the signature was followed by the letters M.B. and some other letters. The woman witness admitted that she had seen Mr. Payne's certificate showing that he was a member of the British Herbalists' Union.

Mr. Payne said in his defence that he had practised for some twenty years but had never pretended to be registered. He was well known and highly respected, and no complaint had ever been made against his character. As a member of the British Herbalists' Union he placed the initials M.B.H.U. after his signature. He saw about 3,000 patients a year and manipulated damaged bones and joints. He admitted that he had never told the woman witness that his certificate was not a medical certificate, and said that his certificates had been accepted for exemption from fire-watching. He called witnesses who said that they had never thought he was registered. The magistrates found all the four charges proved (two charges relating to two

patients each) and imposed a fine of £1 on each, with no order as to costs. The Bench may have had in mind, among other authorities, the case of *Jutson v. Barrow* (1936), in which the use of the words "manipulative surgeon" by an unregistered person were held by the High Court to be a breach of the Medical Act.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

In a Congregation held on Aug. 3 the following medical degrees were conferred:

M.D.—*In person*: A. M.-M. Payne, G. E. Burton, P. T. Cooper, R. McL. Todd, K. G. Bergin, A. C. Thackray, E. M. Darmady, J. Murray.

M.B., B.Ch.—*By proxy*: G. L. Leathur, W. D. Mail, J. S. Rivers, O. C. A. Scott, H. C. Churchill-Davidson, P. S. Davis, E. C. Glover, M. K. Towers, J. Vallance-Owen, R. J. Williams, W. R. Wardill, J. R. B. Dixey, T. C. Gibson, K. E. Jefferson, P. Rhodes, I. W. Whimister, A. G. Jessiman, S. Vakil, D. M. C. Ainscow, W. McC. Edgar, J. B. Frost, M. Henning, E. M. James, D. V. Milward, D. R. Smith, D. R. Wallace-Jones, D. B. Wallis, H. Whimister, E. H. W. Burt, D. J. Crockett, L. Haas, P. S. Hall, D. R. Morgan, H. W. Trusted, A. C. Franks, J. G. Selwyn, M. Shirley, W. van't Hoff, J. W. Coleman, K. E. Marsh, R. J. D. Temple, D. K. Briggs, A. W. I. Hall, J. S. Swallow, G. S. Andrew, W. J. Hay, C. Melver, E. P. G. Michell, D. T. Milnes, A. H. Littlewood. *In person*: A. V. G. Bibby, B. H. Brock, P. L. M. M. Ormerod, H. B. Whitmore, J. A. Bulleid, L. D. E. Cullington, C. E. D. Taylor, R. Randall, S. L. Heitherington, J. D. Lever, R. H. G. Lyne-Pirkis.

Titles of degrees were conferred by diploma on the following members of Girton and Newnham Colleges during July: C. M. E. Jones, M.B., B.Ch. (Girton); G. A. Meigh, M.B., B.Ch., Mrs. M. H. Miller, M.B., B.Ch., and Mrs. A. M. P. Pantin, M.B., B.Ch. (Newnham).

The E. G. Fearnside Scholarship has been awarded to Lionel Wolman, M.B., B.Ch.

UNIVERSITY OF EDINBURGH

Richard White Bernard Ellis, M.D., F.R.C.P., director of the Department of Child Health at Guy's Hospital, has been appointed to the Edward Clark Chair of Child Life and Health in the University, in succession to Prof. Charles McNeil, M.D., F.R.C.P., who is due to retire on Sept. 30.

UNIVERSITY OF LONDON

Ian Aird, Ch.M., F.R.C.S.Ed., has been appointed to the University Chair of Surgery tenable at the British Postgraduate Medical School as from Oct. 1.

Benjamin Stanley Platt, M.Sc., Ph.D., M.B., Ch.B., has been appointed to the Chair of Human Nutrition tenable at the London School of Hygiene and Tropical Medicine.

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *Middlesex Hospital Medical School*; Dr. D. Slome (Physiology). *Westminster Hospital Medical School*; Dr. R. M. Haines (Pathology, Morbid Anatomy and Histology). *British Postgraduate Medical School*; Dr. Mary Barber (Physiology). *St. Thomas's Hospital Medical School*; Dr. H. H. Haines (Anatomy).

Appointments of house-physician and junior assistant medical officer at North-Middlesex County Hospital have been approved for the purposes of the M.D. examination (Branch I).

An additional examination for the Diploma in Public Health will be held in March, 1947. The following have been added to the areas approved for the purpose of instruction in public health administration for the Diploma examination: Metropolitan Borough of Stepney, Municipal Borough of Twickenham.

Major R. G. Gayer-Anderson, R.A.M.C. (ret.), who died on June 16, 1945, left as a bequest to the University his collection of classical antiquities. The bequest has been accepted, and the collection, which was formed almost entirely in Egypt, will be housed at University College in close proximity to the College's collection of Egyptian antiquities.

London Hospital Medical College

The following entrance scholarships have been awarded at the London Hospital Medical College: "Price" Entrance Scholarship in Science, value £100, H. O. Phillipson; "Price" University Scholarship in Anatomy and Physiology, value £100, E. W. P. Jones (Emmanuel College, Cambridge); Open University Entrance Scholarship, value £100, D. S. H. W. Nicol (Christ's College, Cambridge) and P. G. J. Stevin (Jesus College, Cambridge) (equal, scholarship divided).

UNIVERSITY OF SHEFFIELD

Prof. Colin Pantton Beattie, M.B., Ch.B., D.P.H., has been appointed Professor of Bacteriology in succession to Prof. Wilson Smith, who recently left the University to occupy the Chair of Bacteriology at University College Hospital Medical School, London.

COMBINED HOSPITALS UNIVERSITY ENTRANCE SCHOLARSHIPS

The following awards have been made:

St. Bartholomew's Hospital: R. P. Holmes, Trinity College, Cambridge (Scholarship); J. G. Widdicombe, New College, Oxford (Exhibition).

Guy's Hospital: J. G. Armstrong, Queen's College, Oxford (Exhibition); the Scholarship was not awarded.

St. Thomas's Hospital: E. H. R. Ford, Clare College, Cambridge and J. B. Self, Gonville and Caius College, Cambridge (Scholarship jointly); the Exhibition was not awarded.

The Services

DEATHS IN THE SERVICES

Col. HUGH MURRAY MORTON, C.B.E., D.S.O., R.A.M.C., retired died, aged 73, at Berwick-on-Tweed on August 7. He had a distinguished career and saw much active service. He was born in Cumberland and educated at the Grosvenor College, Carlisle, and at Edinburgh University, where he graduated M.B., C.M. in 1896. After holding an appointment as house-surgeon in Carlisle, he entered the Army Medical Service, as it then was, in 1898 and served in the South African war from 1899 to 1902, when he took part in the Relief of Ladysmith and in the campaigns in the Orange Free State and the Transvaal. He was awarded the Queen's medal with five clasps and the King's medal with two clasps. Later he served throughout the first world war of 1914-18, first in the Gallipoli campaign from the initial landing to the evacuation, and subsequently in Egypt and Mesopotamia. He was A.D.M.S. of the 13th Division in Mesopotamia 1916-19 and was awarded the D.S.O. in 1917 and the C.B.E. in 1919, together with the 1915 Star and other medals. After his retirement he lived at Berwick-on-Tweed, where his wife survives to mourn his loss. He had been a member of the British Medical Association since 1897.

AIRBORNE MEDICAL SOCIETY

It has been decided to form a permanent Airborne Medical Society. Membership will be open to all medical and dental officers who are entitled to wear the maroon beret. Particulars may be obtained from the honorary secretary, Mr. Guy Rigby-Jones, M.C., F.R.C.S.Ed., 63A, Belsize Park Gardens, London, N.W.3.

Medical News

The Medical Women's International Association will meet in London in September. The London Association of the Medical Women's Federation will hold an evening reception for the council and delegates at the London School of Medicine for Women (8, Hunter Street, W.C.), on Thursday, Sept. 19, from 8 to 10 p.m. It is hoped that as many as possible of the members of the London Association will attend. Over fifty delegates are expected from all parts of the world. Those who wish to be present are asked to inform the hon. secretary (Miss Josephine Barnes, F.R.C.S., 7, Wimpole Street, W.1) before Sept. 15.

The meeting of the London County Council on July 2 had before it the recommendations of the General Purposes Committee on salaries. The Committee took note of the Government's White Paper on departmental salaries issued in September, 1945. It recommended that the salary of the Medical Officer of Health of the L.C.C., Sir Allen Daley, should be increased to £3,500 a year, this recommendation being personal to the present holder of the office and to be reviewed when the time comes to make a new appointment. The figure of £3,750 is proposed as the salary of the Clerk of the Council.

A quarterly meeting of the Franco-Anglo-American Medical Society will be held at 11, Chandos Street, Cavendish Square, London, on Tuesday, Sept. 10, at 2.30 p.m., with Lord Horder in the chair.

A clinical meeting of the Medical Society of the L.C.C. Service will be held at Queen Mary's Hospital, Carshalton, on Wednesday, Sept. 4, at 3 p.m. Demonstrations of the work in the various units will be given, and discussion on selected subjects will follow.

The annual general meeting of the London Association of the Medical Women's Federation will be held at B.M.A. House, Tavistock Square, W.C., on Tuesday, Sept. 24, at 8.30 p.m., when Dr. Henriette A. Lohr (Amsterdam) will speak on "Medicine in Holland under German Occupation."

The next meeting of the Zoological Society of London for scientific business will be held on Tuesday, Oct. 8, at 5 p.m.

In Gastric Hyperacidity

Rx

'NEUTRALON'

'NEUTRALON' can be confidently prescribed in cases requiring immediate relief pending the restoration of normal gastric function.

'Neutralon' is antacid, adsorbent and slightly astringent, thus excessive acid secretion is both neutralised and retarded. 'Neutralon' does not produce alkalosis, systemic disturbance or purgation, but induces normal digestion.

'NEUTRALON' is the registered name which distinguishes synthetic aluminium sodium silicate of British Schering manufacture. Literature gladly sent on request.

TREATMENT OF ANÆMIA

with

COLLIRON

(colloidal iron hydroxide)

Colliron provides iron in a palatable and assimilable form for the treatment of iron deficiency anæmias and for supplementing dietary intake, particularly in invalids, expectant and nursing mothers.

Colliron is colloidal iron hydroxide with copper, cobalt and manganese. Each drachm contains the equivalent of 6 grains of metallic iron or 32 grains Ferri et Ammonii Citras.

Issued in Bottles of 4 oz., 8 oz., 40 oz. and 80 oz.

Colliron capsules containing iron, nicotinic acid and aneurine hydrochloride are also available.

Issued in Bottles of 30 and 250 capsules.

WITH

Nupercaine

(α -butyloxycinchonic acid diethylethylenediamide HCl or base)

"Fortunately, Nupercaine is a complete substitute for cocaine." Practitioner, 1936, 136, 509.

NUPERCINE LOZENGES

each containing 1 mg., produce a prolonged anaesthesia of the mucous membranes of the mouth and throat, alleviate the discomfort of sore throat and allay post-tonsillectomy distress. (Boxes of 15 and bottles of 100)

NUPERCINE 2% SOLUTION

for anaesthesia of the mucous membranes of the ear, mouth, throat and nose. May be employed topically in proctology. (Bottles of 30 c.c.m.)

NUPERCINE OINTMENT

a 1 per cent. ointment producing prolonged analgesia in chaps, herpes zoster, burns, sunburn, anal fissure, haemorrhoids, pruritus. (Tubes of 1 oz.)

NUPERCINE SUPPOSITORIES

each containing 0.012 g., may be employed in the treatment of anal fissure, and painful haemorrhoids or post-operatively where a prolonged action is desired. (Boxes of 5)

NUPERCINE LUBRICANT

an efficient anaesthetic lubricant containing 10%, for use with tracheal tubes only, facilitates introduction and renders their presence more tolerable. (Containers of 1 oz.)

Vitamins in disorders of the circulation

The following are suggestions for the application of vitamin therapy in certain disorders of the circulation. Space limits the conditions that can be dealt with here but a sequel will appear in the next issue of the Journal.

Condition	Indications	Therapeutic Agents
CARDIAC CONDITIONS Beri-beri heart Congestive fail- ure with oedema associated with mild degrees of vitamin B ₁ de- ficiency	Vitamin B ₁ is needed for both these con- ditions possibly in high doses.	VITAMIN B ₁ (Aneurin Hydrochloride). Ampoules : 10, 50 or more mg. daily. Tablets : 3 mg. twice or thrice daily. BEFORTISS B Complex Capsules or BEMAX to supply the other factors of the B complex.
CIRCULATORY DISORDERS without congestive failure, e.g., Varicose veins	Vitamin B ₁ in high doses has been found to relieve pain.	VITAMIN B ₁ (Aneurin Hydrochloride). By injection or by mouth. 10 mg. or more daily.
SECONDARY EFFECTS Hepatic Diseases obstructive jaundice Ulcerative Colitis.	Low prothrombin is here associated with defective absorption of vitamin K from the absence of bile salts in the intestine. Where fat absorption is defective.	VITAMIN K. One tablet daily with bile salts. VITAMIN K. One tablet daily.

IN SPASTIC CEREBRAL PARALYSIS

In 42 patients with chronic spastic cerebral paralysis, 'Prostigmin' decreased spasticity, restoring voluntary motions long absent, increasing strength, improving in athetosis, ataxia, dysphagia, dysarthria, facial paralysis, motor aphasia and in proprioception from a variety of types of lesions of the brain. Improvement was maintained after discontinuation of therapy.

Dosage varied from one ampoule 'Prostigmin' (0.5 mg.) with atropine sulphate gr. 1/200 to 3 ampoules (1.5 mg.) with atropine gr. 1/100. In a few cases oral dosage was used to supplement the injections. (*Jour. Nerv. and Mental Diseases*, 1946, 103, 107.)

'PROSTIGMIN'

PARASYMPATHOMIMETIC

'Prostigmin' is supplied for injections in 1 c.c. ampoules (0.5 mg.) and a concentrated solution 5 c.c. (2.5 mg. per c.c.), for oral use in Tablet of 15 mg.

ANAHÆMIN B.D.H.

Dakin and West's Erythropoietic Fraction of Liver

Clinical experience over a decade has established remarkable hæmopoietic activity of Anahæmin B.D.H. in pernicious and other macrocytic anæmias. The potency of Anahæmin B.D.H. is such that it is effective in small doses at comparatively infrequent intervals both in the initial treatment of pernicious anæmia patients and their subsequent maintenance.

Further, adequate (but still economical) dosage of Anahæmin B.D.H. is efficient in preventing the appearance and in arresting the progress of subacute combined degeneration of the cord and in eliminating those of the signs and symptoms which are remediable. Further information is available on request.

MENLEY & JAMES LTD.
123 COLDHARBOUR LANE, LONDON, S.E.5

The Minister of Health, Mr. Aneurin Bevan, has approved the appointment of Mr. H. Symon to be Under-Secretary (Housing) in the Ministry, and of Miss Enid Russell-Smith to be an additional Under-Secretary, Health Services Division. Mr. Symon succeeds Miss Evelyn Sharp, who has been appointed Deputy Secretary of the Ministry of Town and Country Planning.

The following officers were elected at the annual general meeting of the Central Council for Health Education: *President*, Lord Woolton; *Vice-presidents*, Sir W. Allen Daley and Dr. Charles Hill; *Chairman of Council*, Mr. Henry Lesser; *Vice-chairman*, Dr. E. K. Macdonald; *Honorary Treasurer*, Mr. E. G. Savage.

The Secretary of State for the Colonies has selected Dr. J. W. P. Harkness, Director of Medical Services, Nigeria, to be Medical Adviser to the Comptroller for Development and Welfare in the West Indies.

In our advertisement columns this week the Royal Melbourne Hospital is inviting applications for the appointment of pathologist to the hospital, at a salary of £1,500 per annum.

The Council of the British Dental Association, meeting in London on Aug. 14, unanimously rejected the proposals relating to dentistry in the National Health Service Bill.

EPIDEMIOLOGICAL NOTES

Typhoid Epidemic

In the week ended Aug. 3 notifications of the enteric fevers were the largest for five years. This increase was due, of course, to the outbreak of typhoid originating at Aberystwyth on July 11. Up to Aug. 21 notifications in Wales had increased to 124, and there had been only two fatal cases—one at Aberystwyth and another at Llanelly. There are now 11 cases infected at Aberystwyth in hospital at Birmingham, and a man of 75 has died. Another death was at Tredegar. Other cases have been reported from Shropshire (3), Hereford (3), and Merthyr (2). The total number of cases in hospitals all over England remains uncertain, but the outbreak appears now to be on the decline.

There are 27 cases of paratyphoid B, including 22 children, in the Halifax Isolation Hospital at Northowram. The precise origin of this outbreak is not yet known.

Anterior Poliomyelitis

The mild seasonal outbreak of poliomyelitis which began last month still persists. Altogether there have been 19 cases, at Barnet, East Barnet, and Potters Bar. Hendon has had 13 cases with 1 death in the last 8 weeks; only 3 of the cases were adults; 3 cases have also been reported from Wembley.

The most recent epidemic in the U.S.A. is in Colorado, where 210 cases have been notified, 104 of them in Denver.

Discussion of Table

In *England and Wales* infectious diseases were less prevalent. There were decreases in the incidence of whooping-cough 376, measles 201, diphtheria 62, scarlet fever 54, and dysentery 31. The only increase was in the notifications of typhoid 52.

A fall in the incidence of whooping-cough was general throughout the country, but the decrease was greatest in the North and especially in Yorkshire West Riding 78 and Lancashire 73. The chief changes in the incidence of measles were decreases in London 102, Kent 58, Durham 52, Lancashire 52, and Warwickshire 43, with a rise in Middlesex 56. The local trends of scarlet fever fluctuated, and the largest variations were an increase in the number of cases in Staffordshire 25 and a decrease in Middlesex 21.

Notifications of diphtheria reached a new low record, which was 1 less than the record of a fortnight ago and 100 less than the lowest weekly return of 1945. The largest decreases during the week were those of Lancashire 27, Glamorganshire 11, and Warwickshire 11.

In *Scotland* the only changes of any size in the notifications of infectious diseases were an increase of 42 in cases of scarlet fever and a decrease of 63 in the notifications of measles. The rise in scarlet fever was general throughout the country.

In *Eire* a fall was recorded for measles 24, diarrhoea and enteritis 13, and diphtheria 9.

In *Northern Ireland* an increase of 13 cases in whooping-cough was reported from Belfast C.B.

Week Ending August 10

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 707, whooping-cough 1,910, diphtheria 243, measles 3,299, acute pneumonia 298, cerebrospinal fever 34, dysentery 84, acute poliomyelitis 18, paratyphoid 13, typhoid 89.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 3.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Atiology Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Articulate Westcent, London*.

MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Essential Hypertension

Q.—*A single woman suffers from a severe form of hyperpirosis (B.P. 260/110). This was recognized nine months ago; the symptoms were loss of weight and strength, headaches, and attacks of indigestion with or without vomiting. The case was considered unsuitable for renal sympathectomy, and she was treated medically with potassium thiocyanate and luminal 1 gr. (65 mg.) twice daily and rest. She has improved and ceased to lose weight, and can do a half-day's office work, though her B.P. is still high (225/100). Can you suggest any other treatment?*

A.—So far as can be judged from the data given, this patient is suffering from essential hypertension. If the investigations showed little or no impairment of renal function the hypertension cannot be of the malignant type; moreover, a patient who has had malignant hypertension for at least nine months would not be showing improvement in her condition. Do the age and the circumstances in this case indicate any menopausal element in the aetiology? If so, it would be worth while to try ovarian substitution therapy. There are no known medications which can be relied upon to lower blood pressure for more than brief periods. The only operative treatment available for patients found to have no unilateral renal lesion is the extensive sympathectomy advocated by Smithwick. The results to be expected from this operation depend upon the pulse pressure being relatively low. As good results are likely only when the pulse pressure is about half the diastolic pressure this patient would be unlikely to benefit. Treatment in the present will therefore consist in an appropriate regimen and automatic remedies, coupled, if the renal function is at all reduced, by a restriction of protein in the dietary. The prognosis depends upon the age and the cause. The younger the patient the worse the outlook; conversely, if the patient is, say, 50 years of age and at the climacteric the prospect is correspondingly more hopeful.

The Tobacco Habit

Q.—*Is there an effective cure for the tobacco habit? What is the method advocated by advertised "cures"?*

A.—The "tobacco habit" is due to a composite of motives, often opposite ones. The obvious physiological advantage is that by the paralysis of nerve-endings it soothes the organism when in a state of excitation. On the psychological side a youth usually takes to smoking because he feels it to be big and manly, or the girl because it is sophisticated and grown up, a gesture of emancipation. But analysis of these cases proves that there is a more fundamental and opposite motive of smoking, and that is a sucking tendency. Many men, will, therefore, suck their pipes when they have no tobacco, and a straw if they are without a pipe. It is a movement away from life, and a return to infantile life. The cases of chain smoking we have analysed (see *Journal*, 1945, 1, 793) all reduce themselves to a regression to oral erotic tendencies in infancy, which were arrested in development because of the feeling of lack of love, the sensuous pleasure being resorted to as a substitute for the mother's breast and a solace for the loss of love. The

"soothing" qualities of smoking so often ascribed to the effect of nicotine on the nerve-endings is probably more often due to this reversion to an infantile solace.

We have no first-hand knowledge of the use of the advertised cures; but there is no reason why some drug which so affects the tongue and palate that the tobacco is made distasteful should not succeed, just as some men find smoking distasteful when they have a bad "cold." It does not cure the cause, but by breaking a vicious circle for the time being it may enable the victim to overcome it. The same applies to suggestion—mode of treatment which is unfortunately dying out in the face of the more radical analytic treatment, but which has its very definite uses in psychotherapy.

Respiratory Murmur

Q.—*Can you explain why the respiratory murmur can be heard much better in some normal patients than in others irrespective of the thickness of the chest wall?*

A.—The cause of the normal respiratory murmur is not exactly known, but it probably consists of two elements. (1) Vibrations produced by the air passing through the glottis; these are transmitted along the bronchial tree and become fainter towards the periphery. (2) Vibrations produced by the air passing from the small terminal bronchioles into the larger air sacs. The position of the vocal cords influences the volume of the respiratory murmur, and so does the depth of respiration. Variations in these two factors, particularly in the depth of breathing, account for the differences in the respiratory murmur in normal individuals. It must also be remembered that emphysema suppresses the respiratory murmur, and that some degree of emphysema is very common, especially in later life.

Specks before the Eyes

Q.—*What is the cause of floating specks before the eyes, and is there any remedy? A patient describes them as "small finger-prints." I believe they are technically called "muscae volitantes."*

A.—Floating specks before the eyes are usually due to a liquefaction of the vitreous and are caused by the conversion of the normal colloid gel into a sol. The cause of this change may be due to physico-chemical factors, enzymic digestion of the protein bases of the gel, or a degeneration as in senile and myopic eyes and after contusion of the globe. There is no real remedy, though a mixture with 2 gr. (0.13 g.) of potassium iodide in it may be given by mouth twice a day for a month or so. Improvement has been reported after such treatment, but may be due to the "specks" having moved to a position where they are no longer noticed by the patient. Proper correction of errors of refraction also tend to make the "specks" less distinct to the patient. Any focus of sepsis should be sought out and dealt with to prevent further possible vitreous changes.

Should Women Wear Corsets?

Q.—*Apart from aesthetic considerations, what are the general and specific indications for wearing corsets? What is the authoritative view on designs and materials, and at what age should children or young women be introduced to the practice? I would also appreciate a note on how far brassières and suspender belts are recommended as articles of wear.*

A.—In my opinion, apart from aesthetic considerations, there are no general and specific indications for the healthy female to wear corsets. In later life, and after abdominal operations or repeated childbirth, women often state that the support afforded by a corset is helpful and reduces fatigue. But it seems a pity that so many women become dependent on a corset support when massage and remedial exercises would be of more benefit.

It is well to point out that the modern idea of a "corset" is very different from the old. The modern "foundation garment," if well made, and especially if made to fit the individual for whom it is intended, is comfortable to wear and has no disadvantages of undue pressure or restriction of movement. It is such a help aesthetically in so many cases that it is to be recommended, especially in the late thirties and onwards. Earlier, nothing of this kind should be required, but many

olescent girls and young women are advised to wear brassières. With the brassière a narrow hip suspender belt can be worn to support stockings if required. Should a corset be thought necessary for younger women the corselette type is often recommended—to be worn over the vest and not next to the skin, and washed frequently.

These matters are discussed in health education courses in schools and colleges, but it is helpful for women school medical officers to have a word with individuals at school medical inspections. More notice is taken of this individual advice than of that given in lectures or classes.

Meulengracht Diet

Q.—What are the details of the Meulengracht diet for haematemesis?

A.—Meulengracht in 1934 reported his experiences of "the treatment of haematemesis and melaena with food" (*Acta med. scand.*, 1934, *Suppl.*, 59, 375). The details of his regimen, which are set out below, are given in his article, and repeated in later papers: *Lancet*, 1935, 2, 1,220; *Wien. klin. Wschr.*, 1936, 49, 481.

From the day of admission the following diet is taken:

- 6 a.m. Tea; bread-and-butter.
- 9 a.m. Oatmeal with milk; bread-and-butter.
- 1 p.m. Dinner: Main dish (meat or fish balls; *timbale*: broiled chops; omelette; meat, fish, or vegetable *gratiné*; mashed potatoes; vegetable *purée*), with either soup (vegetable soup or cream of vegetables) or sweet (stewed apricots, apple *purée*, gruel, rice or tapioca pudding).
- 3 p.m. Cocoa.
- 6 p.m. Bread-and-butter; sliced meats; cheese; tea.

Only white bread is served, and milk can be taken between meals if desired. The patient is allowed to eat as much as he wishes, and the average calorie value is about 2,300. An alkaline powder (sod. bicarb. 15 g., mag. subcarb. 15 g., ext. yoscyami 2 g.; one teaspoonful t.i.d.) and iron (ferrous lactate 0.5 g. t.i.d.) are administered from the first day. The patient is allowed to move about freely in bed, and usually starts to get up after two or three weeks. The average period in hospital in Meulengracht's patients was five weeks; on discharge they were advised to continue the medicines for six weeks and the diet for six months.

The Meulengracht regimen in its original form has probably not been widely used in this country, although the principle on which it is founded now commands general assent. The excellent modification by Witts is followed in many hospitals; full details can be found in this *Journal* (1937, 1, 847). Avery Jones (*ibid.*, 1939, 2, 332) has stressed the importance of an adequate intake of fluid and salt for these patients—a point neglected by Meulengracht.

Syphilis: Criteria of Cure

Q.—A patient of 56, who was cured of G.P.I. by malaria 20 years ago, now has a normal C.S.F. but the blood W.R. is + +. He is free from symptoms and signs other than fixed pupils and absent knee-jerks. Is further antisyphilitic treatment indicated, and, if so, what?

A.—No further antisyphilitic treatment is indicated: a normal cerebrospinal fluid so long after apparently successful treatment is the best possible guarantee of arrest of the disease. The positive blood Wassermann may be ignored. See a paper read by Dr. W. D. Nicol and Dr. Maevé Whelen before the Medical Society for the Study of Venereal Diseases, April 27, 1946 (in the press).

Puberty Epimenorrhoea

Q.—A healthy girl of 18 has her periods at three-weekly intervals, with no increased flow, pain, etc. Is there any known cause for this periodicity, and what modern treatment is recommended?

A.—There is not necessarily anything wrong with this patient, for a regular cycle of anything between 21 and 35 days is usually regarded as being within normal limits and peculiar to the individual concerned. Nevertheless some degree of

epimenorrhoea, clearing up spontaneously a little later in life or after pregnancy, is not uncommon in young girls. Sometimes it is associated with mild hypothyroidism or with pelvic congestion due to sedentary habits, chronic constipation, or sexual excitement. Often, however, there is no obvious cause, and it is assumed to be a mild functional disorder situated primarily in either the pituitary or the ovary. A small regular dose of thyroid is one of the best treatments for puberty epimenorrhoea, but it is doubtful whether any treatment at all is required in this case.

INCOME TAX

"1½ Years' Purchase"—Basis

IGNORAMUS inquires what precisely is the basic figure which is taken in the case of the sale of a practice at "1½ years' purchase"?

* In general parlance the phrase implies 1½ times the gross receipts of the practice. For example, if the gross receipts have been £2,400, the expenses £900, and tax has been paid on the balance of profit (£1,500) to the amount of £600, "1½ years' purchase" would mean 1½ times £2,400—i.e., £3,600.

Increased Share in Practice

A. M.'s share was increased from 1/3 to 1/2 as from April, 1945. On what basis should he pay tax for 1945-6?

* The practice is assessed as a unit on the basis of the profits for the previous year, but that assessment is divisible between the partners according to their shares for the actual year. In A. M.'s case he is liable to account for tax on one half of the assessment for 1945-6.

Purchase of Share in Practice

J. W. purchased a third share in a practice as from March 1, 1946. How should the tax assessed for the year to April 5, 1946, be divided between himself and the out-going vendor of the share?

* J. W. will be liable to account for tax on one third of 36/365 of the gross assessment on the practice. He can, however, deduct therefrom any allowances or reliefs due to him for 1945-6 and not allowed from any other item of his income.

"A practitioner starting in a practice" cannot claim the "cash basis" concession; but as the practice is the unit to be assessed, and is presumably not being treated as "new," the question does not arise in J. W.'s case.

First Year of Assistantship

B. H. is about to commence as an assistant in general practice at a salary of £x a year, and will have to find and run his own car and rent a flat. The practice is carried on at a central surgery.

* He will be able to claim the "initial" and depreciation allowances on the car, and the cost of upkeep of (but not the original outlay on) such instruments, etc., as his service agreement requires him to provide. As regards the rent of the flat and such general expenses as telephone, domestic service, wages, etc., he can claim to deduct the additional expense attributable to professional use, but on that basis he is not likely to obtain a substantial deduction.

War Damage Contribution

J. owns the freehold of a house which has been requisitioned by the Ministry of Health and converted into flats. As a result, the assessment on which War Damage contribution is payable has been increased from £40 to £120. The amount of compensation received for the requisitioning of the property is £90 per annum. Is J. liable to pay the increased contribution?

* Yes. The liability attaches to the direct contributor, i.e., the person who has a proprietary interest subsisting in the property, and J. apparently owns that interest. War Damage contributions turn on ownership, not on the way in which in any particular year the income from the property is shared. There are exceptions to this rule. Where there are tenancy rights extending over a period of years, the direct contributor can claim a partial indemnity from his tenant, but on the facts quoted this does not assist J.

Non-resident Appointment: Car Expenses

F. asks whether the cost of running a car between his residence and a hospital, at which he holds a whole-time non-resident post, can be deducted for income tax purposes?

* No. The rule is strictly construed, and the expense of travelling between the residence and the place where the duties of an appointment are performed is not regarded as incurred in the performance of those duties.

Absence Abroad: War Loan Interest: Car Transactions

T. F. was abroad in the Army from Jan., 1941, to Jan., 1945; and from Jan., 1941, to Aug., 1943, his wife was domiciled in Northern Ireland, his house being let furnished. Can he claim exemption on War Loan Interest?

** On the facts stated it would seem that T. F. was "domiciled" and "ordinarily resident" in the United Kingdom, and therefore is liable to tax on the War Loan Interest.

Claims can be made for the "initial allowance" and "depreciation allowance" on both cars bought by T. F. since demobilization. The claims for the car bought in Jan., 1946, will be for the financial year for which tax is assessed on the profits made in the period which includes April 6, 1946; the claims for the car bought on May 16, 1946, will be for the financial year for which tax is assessed on the profits of the period including that date.

Car Transactions

G. H. bought a car for £350 in 1938 while in practice. He sold his partnership share in March, 1940, stored the car, and joined the R.A.M.C. He was released in Feb., 1946, and recommenced practice in Aug. or Sept. The present estimated value of the car is £650. Will the future depreciation allowance on the car be based on its cost (£350) less the allowances given so far, or can the value be substituted in calculating the allowance? If the former, may it not be advisable to sell the present car before recommending practice?

** The depreciation allowance is intended to give relief in respect of the wastage of capital sunk in buying the car, and the capital amount on which the allowance is calculated will therefore be based on the amount expended and not on any estimate of present value. From an income tax point of view it would seem advisable for G. H. to sell his present car before recommending practice, but obviously other factors enter into his decision. For instance, if he holds the car for another year or so both the "balancing charge" and the cost of a new car might be materially less than at present.

A. R. bought car "A" in 1938 for £205, was called up in Aug., 1939, and sold the car for £145 in July, 1942. At the same time he bought car "R" for £320. He resumed practice on Oct. 1, 1945. (a) What, if anything, can he claim in respect of the transactions, and (b) what allowance can he claim for the period after Oct. 1, 1945?

** (a) As the sale and purchase took place during the discontinuance of the source of income to be assessed, there appears to be no basis for any claim to a deduction for the money then spent.

(b) Depreciation allowance can be claimed on car "R," for the half year from Oct., 1945, at 20% plus one-fifth, i.e., 24% per annum, and for the year 1946-7 at 25%. With regard to the capital basis, A. R. cannot put it higher than £320, the actual cost of the car—the income tax authorities may claim to put it at £320 less the national wear-and-tear allowance for the period from the date of purchase to Oct. 1, 1945.

P. (a) bought a car in 1935 for £140 and sold it in March, 1946, for £100, the written-down value then being £8. Is a "balancing charge" due? And (b) bought a car in March, 1946, for £371. Can he claim an "initial allowance" for 1946-7?

** (a) No—the car having been sold before April 6, 1946; (b) the car must be regarded as having been acquired on April 6, 1946, the first day of 1946-7, and accordingly the initial allowance is due for 1947-8, not 1946-7.

C. R., referring to the reply to "Equity" (July 13, p. 76), asks what is the effect of a "balancing charge"?

** Tax is payable on the amount of the charge, ordinarily as part of the professional profits, at the rate of tax appropriate to the vendor of the car for the year of liability.

Military Pay: Deduction for Cost of Books, etc.

C. R. asks, "What relief can medical specialists in a military service claim in respect of medical journals and books, subscriptions to learned societies, and home telephone which the service require all specialists to have installed in their homes?"

** The matter is governed by the Schedule E rule which forbids the deduction of expenses unless they are incurred "wholly, exclusively, and necessarily in the performance of the duties of the office." The rule is interpreted by the revenue authorities as forbidding the deduction of the sort of expenses indicated unless they are required to be incurred by the terms of the service agreement. C. R. seems to have some claim for the use of his telephone; the position with regard to the other expenses is more doubtful. An appeal can be made to the Income Tax Commissioners for the employing department, and an appeal to the High Court can be lodged against their decision.

LETTERS, NOTES, ETC.**Sites for Intramuscular Injection**

Dr. J. E. O'N. GILLESPIE (Dublin) writes: In the reply to query on sites for intramuscular injection (July 27, p. 147) stated that "experience shows the safe area of the buttock to be far and away the best site in the body for intramuscular injection. I think that the lateral aspect of the thigh is, in general, by far away the best site for intramuscular injection and that the use of this site should always be taught to medical students and nurses. Your respondent points out, injection can be given there with danger; but he adds that it is usually more painful than if given in the buttock. I doubt if this be so, although I cannot produce evidence to support my view. The risk of injury to the sciatic nerve when the injection is given in the buttock is real; although obviously it implies lack of knowledge on the part of doctor or nurse.

Effects of Sweets on Teeth

Miss MARY THOMAS (Oxford) writes: I have been interested in correspondence on the effect of sweets on teeth because my grandmother, who was born about 1854 and died at the age of 76, a fixed habit of always eating a small piece of chocolate the thing at night after getting into bed, and had the most perfect teeth throughout her life of anyone I have known. As a matter of routine she went periodically to the dentist, but was never given treatment as she never needed any. This unusual degree of dental health was not transmitted to any of her seven children or eleven grandchildren, all of whom have quite ordinary troubles with their teeth. It is possible that this may be due to dietetic causes. My grandmother was a child crops were still grown by wholly organic farming methods, and it is contended by many modern authorities that the food produced in this way has more vitality, and that those who eat it have greater resistance to disease, than food grown with artificial, chemical fertilizers, as has for many years now been accepted farming practice. Nutritionists would find the recent published *Humus—and the Farmer*, by Friend Sykes, of absorbing interest in this connexion, since he gives the results of his experiments in organic food production, over many years, upon the health of plants, farm animals fed on such food, and on his own health. Among other things he says that the formation of teeth on his teeth ceased completely after eating whole-wheat bread made from grain produced on his farm by organic methods only, for three or four years. He considers that by organic methods of farming, i.e., use of natural manures—a correct rotation of crops and proper tilling of the soil—England could easily produce enough food to feed the whole of her population, and that such food would be of a much higher quality than we eat now.

R.A.M.C. Reunion Dinners

Mr. T. J. DALY (1, Lancashire Road, Bishopston, Bristol) writes: In various sections of the press one reads of reunion dinners, meetings being planned or suggested. Due to the exigencies of a very few Army medical officers could lay claim to any one particular unit. Changes of locality, units, and personnel were experienced quite often by the vast majority. The object of this letter is to effect the formation of an association to enable ex-Forces medicals to perpetuate the comradeship and brotherhood fostered during service. It would not be the intention to hold one reunion dinner, say, in London, where only the fortunate ones can assemble, but to arrange such affairs in regional centres throughout the land. Should any of your readers be interested in this suggestion, I will gladly furnish fuller particulars of a tentative scheme to launch this idea.

In Aid of the Grenfell Mission

Though the claims upon the charity of doctors are as numerous as they have ever been, we would nevertheless draw their attention to an organization particularly deserving of their sympathy and generosity. The Grenfell Mission continues its work of health education, and welfare among the poor of Newfoundland and Labrador; its hospitals and nursing stations in remote places are sole means of bringing help in time of distress to the people and its schools provide the only education to be had by children in isolated settlements. It needs funds urgently. Doctors can help by purchasing their Christmas cards from the Grenfell Association in this country. This year a number of attractive cards in colour are available at 10d. each, and in black and white at 5d. each; a pocket calendar at 7d.; coloured postcards in packets of 6 for 2s.; sepia postcards at 2d. each. For philatelists there are packets of Dominion, Colonial, and U.S.A. stamps, 24 per packet at 1s. They should be obtained from the Grenfell Association, 66, Victoria Street, London, S.W.1, or from Miss Howat, c/o MacLay & McIntyre, Ltd., 125, Buchanan Street, Glasgow, C.1.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 24 1946

IMPENDING HEALTH LEGISLATION IN U.S.A.

Health Bill before Congress

Last November President Truman sent a message to Congress outlining a National Health Programme. He pointed out that millions of United States citizens had no opportunity to achieve or enjoy good health and no security against the unequal economic incidence of sickness. One-third of the men examined for military service had been rejected as unfit, and more people died annually in the United States from preventable diseases than had been killed or had died from injuries during the war. The benefits of medical science, said the President, were not available equally to all. People with small incomes did not command the same medical attention as those who were better off; rural areas were less well served than the towns. He drew particular attention to the unequal distribution of doctors. In proportion to its population the United States has more doctors than any other large country in the world, but large areas are under-doctored. About 1,200 counties in various States, covering a population of some 15 million, have no local hospital or at least none which meets even the minimum standards of the national professional associations.

The President's Programme

The programme submitted by the President contained five basic provisions: (1) federal aid grants for the building of hospitals and health centres throughout the country; (2) extension of maternity and child welfare services; (3) extension of public health services; (4) the establishment of a national science federation for promoting medical research and professional education; and (5) compensation for loss of earnings due to sickness. With regard to this last it is explained that about nine-tenths of such loss is due to illness or accident not directly connected with employment, and therefore not covered by the system of workmen's compensation. The President also suggested in general terms what amounts to a system of compulsory health insurance on a wide basis. At present only about 3 or 4% of the American population are insured for any comprehensive medical care. The President had in mind a scheme which would provide medical services, including hospital and specialist, and also dental care, on payment of a contribution equal to 4% of the first £600 of the insured person's annual earnings. Those so insured should remain free to choose their doctors, and doctors to accept or reject their patients, and freedom to treat and be treated outside the system should be conserved. The President described the American people as the most insurance-minded in the world and not likely to be frightened off a scheme of national health insurance by talk, already current, of "socialized medicine."

Content of the Bill

On the same day as this message was received by Congress, two senators, Wagner and Murray, introduced a new Health Bill embodying a compulsory insurance plan for the nation. The Bill is said to be the idea of Isidore S. Falk, research director of the Social Security Board, and Michael M. Davis, a member of the Political Action Committee of the big industrial workers' association known as the C.I.O. Senator Wagner declared that the Bill was the result of constructive suggestions by many outstanding medical authorities as well as other organizations interested in improving the national health. But it was not denied that no representatives of the American Medical Association had been consulted, although that body includes 125,000 doctors. *The Journal of the American Medical*

Association promptly complained that "typical of the kind of government that the bureaucrat would force on the American people is this technique of consulting the advisers who are known in advance to be in complete agreement with the persons whom they are supposed to advise, and of studiously avoiding anyone who might offer a contrary opinion. This is government by minority with a vengeance."

The Bill is in two parts, or "titles" as they are called in America. The first part consists of three sections, one of them proposing federal grants to States for public health services, another proposing grants for maternity and child welfare services, and the third proposing grants for the medical care of needy persons. The second "title" is the more controversial. It proposes to make available personal health service benefits to insured employees, their specified dependants, and certain other individuals. It does not appear that it is intended to cover 100% of the population; the figure of 80 to 85% is mentioned. Personal health service benefits mean general and special medical and dental benefits, home nursing, laboratory services, and treatment in hospital. Broadly speaking, general medical benefit is represented by the services of the family practitioner, while special medical benefit means the services of consultants or specialists, which will ordinarily be available only on general practitioner advice.

On the administrative side the Surgeon-General of the Public Health Service at Washington will be the head of the service, assisted by a national advisory medical policy council consisting of 16 members, appointed by the Surgeon-General, its chairman; from panels submitted by professional and other organizations. It will be the council's business to advise on general policy and administration, including professional standards and designations, and methods and arrangements. The Surgeon-General will also be responsible for the panels of practitioners accepting service and the lists of persons eligible for benefit. The payment of general practitioners, and of specialists also, may be on a fee-for-service basis, a capitation basis, or a full or part-time salary basis, or a combination of any of these. The method of payment is to be determined in each local area. It may be according to a national scale or may take account of exceptional regional conditions.

Opposition to State Medicine

The proposals have aroused some fierce opposition in the medical profession in the States—opposition which may seem to us, accustomed for a generation to State compulsory health insurance, and now facing a greater revolution in health services, somewhat extreme, but American social history and the freedom of the American medical profession must be borne in mind. The *Journal of the American Medical Association* declares that this is worse than "socialized medicine," the term which President Truman deprecated, it is "State medicine." The Government would collect the funds available, manage the service, and distribute the payments. It is pointed out that the free choice which is said to be ensured is largely a chimera, for the Bill provides that the Surgeon-General, who will be at the head of the service, can limit the number of patients a doctor may see, and provide other doctors when too many patients make the same selection.

A forthright leading article in the *J.A.M.A.* declares that by this measure the doctors of America will become "clock-watchers and slaves of a system." This, it says, is the kind of regimentation which led to totalitarianism in Germany. The prime consideration is deduction from the pay of the worker and taxation of the employer so that the Government can do for the people of the United States most of the things which the people have been accustomed to do for themselves.

¹ At present fewer than half the counties in the States are provided with a full-time public health service.

Actually, however, the method of contribution or tax is not raised in the Bill. An earlier Bill, introduced by the same two senators, did propose a tax or contribution to be levied on employees, employers, and self-employed persons in order to finance the compulsory sickness programme. The new Bill now before Congress, which presumably supersedes the first, imposes no such taxation, merely laying it down that the service will be financed by appropriations from the general fund. The original proposal was 3% on wages, one half to be contributed by the employer and, the other half by the employee. The opponents of the Bill see in the dropping of these proposals an attempt to by-pass the congressional committees which in both the Senate and the House have jurisdiction over any legislation imposing taxes. The reply of the promoters is that it has been done merely to expedite public business.

The Bill in Committee

After its introduction into the Senate the Bill was referred to the Senate Committee on Education and Labour, of which Senator Murray, one of the promoters, is chairman. Here it has received a close examination. The method followed in Senate committees, unlike that in the Standing Committee of our own House of Commons, is to hear statements and take evidence from outside witnesses. The proceedings began with long declarations by the supporters of the Bill, in which they denied that the measure would destroy private practice in medicine, fetter the doctor, or upset the voluntary hospital position. The proceedings have not been without acerbity. A good deal of uneasiness has been shown over the position of the Surgeon-General. Witnesses against the Bill have said that the medical profession will be placed under the direction of one man, who will become a dictator. To this Dr. J. W. Mountin, Medical Director of the Public Health Service, replied that the Surgeon-General is appointed by the President, his appointment has to be confirmed by the Senate, he is under the control of the administrator (Minister) who sits in the Government, a report from his department has to be made to Congress annually, he has to come before it for his appropriations, and if anything went wrong and any substantial body of citizens, or even a small number of citizens, made a complaint Congress would very quickly transmit it to the Surgeon-General and call him to account. On the general merits of the Bill Dr. Mountin said that the critics had paid too much attention to certain details and too little to the underlying philosophy. "Heretofore the individual has had to finance his own cost of illness out of his own pocket. This is an attempt to change that process, and, so to speak, lift the cost of illness off the pockets of sick people and place it on the broad shoulders of society." Representatives of several national organizations have given evidence.

Platform of the A.M.A.

Meanwhile, the American Medical Association has announced a programme to improve the health and medical care situation in the United States. It begins by stressing the importance of nutrition, housing, and preventive medical services and the need for health and diagnostic centres and hospitals and a maternity service. It calls for a medical care plan, the costs of which would be met by a voluntary non-profit prepayment system. A body has been already set up to be known as Associated Medical Care Plans, Incorporated, the "members" of which are the various services which conform at least to the minimum standard laid down by the A.M.A. Council, and also permit transference from one service to another. It is pointed out that the medical profession in each area must assume responsibility for the medical services included in the benefits, and at the head of the principles which each such plan must embody are free choice of doctor and the maintenance of the confidential and personal doctor-patient relationship. At present it is estimated that 75% of the population receive no prepaid medical care at all, and only 4% receive any complete care under voluntary health insurance plans. Most of the present medical prepayment organizations give a service limited in coverage and scope, though some special evidence relating to services operating in Washington and Oregon is being, or has been, presented to the Senate Committee; the services in those States are said to approach what is desirable on a national scale.

The reply of the promoters of the Bill is to point out the shortcomings of private or voluntary insurance, the non-

eligibility of large numbers of people, the fact that the plan meet only a section of health needs, the weighting of schemes by the unhealthy and those who anticipate illness, the overlapping and duplication and tendency to high administrative costs which characterize such schemes. According to one witness before the committee, there is no hope of voluntary insurance schemes fulfilling of themselves a comprehensive exclusive medical care programme. But the A.M.A. thinks that along such lines, given the efficient organization and uniformity which a central body could ensure, there is an alternative to a State scheme to which, both from the public and the professional point of view, there are deep-rooted objections.

INTERNATIONAL MEDICAL CONFERENCE

The medical profession of Great Britain has been fortunate during the war years in that its professional and scientific activities have been much less interrupted than has been the case with professional associations on the Continent. The Council of the British Medical Association has taken the view that the Association should give a lead in bringing together the national medical organizations of the various countries. In June, 1945, an unofficial conference was held at B.M.A. House to explore means of continuing the fellowship built up during the war between doctors of different nationalities. Delegates from Belgium, France, Holland, Yugoslavia, Poland, and the United States stressed the need for an international medical organization. The B.M.A. has therefore called an International Medical Conference in conjunction with *L'Association Professionnelle Internationale des Médecins*. The purpose of the Conference is to promote international medical relations, and this may best be achieved by an association of the national medical bodies for the advancement of medicine, including cultural and social aspects, and the promotion of international good will and understanding.

International Policy

The medical profession throughout the world must recognize and accept its responsibility for the world's health. It is especially important at this moment that doctors should be keenly aware of the power, duty, and responsibility of the profession in the international as well as the national sphere. British doctors can give a lead to the whole medical world and encourage doctors in less fortunate countries to exert their influence to avert dangers to world peace and health. The failure of German doctors to attempt to combat the Nazi ideology led to both professional and national debasement, and their own profession became disintegrated.

The attitude and standards of a country's doctors permeate the whole of its social fabric. There is no need for them to engage in politics; they can play their part through service, example, and persuasion. They can promote the recognition of the importance and dignity of the individual and of liberty of thought and action; they can spread knowledge of the basic principles of a healthy and happy life—sound family life, adequate nutrition, good housing, sound mental health, the right use of leisure, the right attitude to environment, and the prevention of disease. They can, in short, help to make the health of the peoples a primary object of international policy. If British doctors will take the initiative, they will not only raise British prestige, but they will help medicine throughout the world to take up its responsibility as a powerful force for peace, health, and security.

Immediate Problems

The immediate problems of international medicine are to rehabilitate the medical profession in European countries and to improve the standards of health of the peoples on the Continent. The solution of the second problem is to a large extent dependent, as a long-term policy, upon the solution of the first, and there is here a great opportunity for the British profession to help its colleagues. The destruction of German and Austrian medical facilities, organizations, and prestige has left a void in Europe. Before the war doctors in Norway

Sweden, Denmark, Holland, Switzerland, and other countries habitually visited German medical institutions, received German medical journals, were conversant with German medical literature, and generally profited by recent work in Germany. This source of assistance and inspiration has now wholly disappeared and the doctors in the liberated countries in western and northern Europe are anxiously looking for an alternative. As English is widely spoken in these countries it should not be difficult for Great Britain to fill the gap.

Between the two great wars, pioneer work in international medical relationships was carried out by the A.P.I.M. During the war this body was no longer able to function, and the time has now come to review and enlarge its work, which will be complementary to that of the new world health organization now being shaped by U.N.O.

Among the activities of an international medical body would be the exchange of teachers, and students, and books, with provision for postgraduate courses and appointments. The two new abstracting journals, *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics, and Gynaecology*, which are to be published in four months' time by the B.M.A., should be of the utmost value in this connexion.

The possibility of a special publication for the international medical body may be considered. The whole subject of an international medical organization will be explored by the Conference to be held at B.M.A. House from September 25 to 27. The following countries have already intimated their intention of being represented: Australia, Austria, Belgium, Bulgaria, Canada, Czechoslovakia, Denmark, Eire, France, Hungary, Netherlands, New Zealand, Norway, Palestine, Peru, Poland, South Africa, Spain, Sweden, Switzerland, and the United States of America. The British Medical Students' Association will also be represented. In addition to the formal meetings there will be a dinner at the Savoy Hotel. The Minister of Health is giving a luncheon reception, and Sir Alfred Webb-Johnson, president of the Royal College of Surgeons, has arranged for the delegates to visit the Middlesex Hospital.

HEARD AT HEADQUARTERS

Friendly Societies and the Doctors' Case

Appreciation of the doctors' case shows itself in rather unexpected quarters, as, for instance, in the High Court of the Ancient Order of Foresters, the second largest friendly society in the kingdom, meeting the other day at Tunbridge Wells. The member of the Executive Council who introduced the discussion on the National Health Service Bill, Mr. E. J. Hicks, who will next year be High Chief Ranger, said that from close touch with the members of the Order, numbering nearly half a million on the voluntary side, it was evident that there was widespread sympathy with the doctors' position. The doctors of the future, he said, would be directed just like the "Bevin boys." Nobody liked direction, and although we had all been pushed hither and thither during the last six years the process became no more agreeable with repetition. Their sympathy was with the doctors, said Mr. Hicks, because they knew how essential was the personal relationship between doctor and patient. Doctors often failed, not because their skill was lacking, but because the patient's trust was not forthcoming. "We believe that the best system is the one we have had for many years past. I am not saying that everything in the medical service was exactly as it ought to have been, but it did give freedom." The Foresters, while welcoming on the whole the National Health Service, were troubled by its effect on certain operations of the friendly societies, notably juvenile medical benefit, which will become a redundant service.

The Minister of Health has made a regulation under the National Health Insurance (Medical Benefit) Regulations providing that a chemist shall not dispense a prescription requiring the manufacture by him of a preparation of penicillin for parenteral injection unless he holds a licence for that manufacture under the Therapeutic Substances Act.

Correspondence

The Representative Body and Regional Boards

SIR,—The antic behaviour of the Representative Body is sometimes more reminiscent of a tribal gathering than the deliberations of a democratic body, evolved after nearly a quarter of a century's experiment. The emotional flash-point of the R.B. is at times so low that any instance of fifth form buffoonery can elicit the loud laugh that speaks the vacant collective mind. And any opportunist hot-head with a persuasive tongue can talk the R.B. round into voting against its better judgment.

A remarkable instance of this folly was the passage of the amendment outlawing the regional boards (Aug. 3, p. 56). This irrelevant amendment to a perfectly sound resolution became a resolution after the second attempt to suspend standing orders. Judging by the figures quoted the required three-quarters majority obtained did not represent a third of the total R.B.; there must have been numerous abstentions and absences. But the effect of this fantastic resolution, so-called, if rigidly implemented, will be to hamstring the labours of the Negotiating Committee over the past two years, and to remove from the hospital-planning agencies that authoritative medical influence we have all been working for. Moreover, the wording of the resolution is so comprehensive that it excludes as well the university representatives, the professors of medicine and surgery, and the deans of medical faculties. Are these men likely to sacrifice the interests of their university on the regional boards at the dictation of the R.B.? Incidentally, is the B.M.A. to legislate for every medical practitioner? Surely it is assuming powers that properly belong to the G.M.C.

This resolution not only cuts off our nose to spite our face, but hands it on a plate to the Minister. If the medical profession and universities won't play ball on the regional boards, who will be jumping with glee?—the local authorities and the trade union movement.

No; the sooner this unhappy resolution lies accumulating dust on the table, the better. And to prevent such incidents in the future the machinery of the R.B. must be re-devised. The report of the agenda committee in response to the Winchester resolution was a model of democratic theory, but in practice the procedure is not working efficiently. The R.B. is too large a body to sustain collective responsibility for more than a few hours, and it must be protected from its tendency to lapse into tribal mass hysteria by tightening up the standing orders and adapting these so that the loophole of suspension of standing orders does not arise.—I am, etc.,

Bristol.

FRANK BODMAN.

Delayed Release of Specialists

SIR,—We wish to urge in the strongest terms the speeding-up of the demobilization of specialists in the Forces. Under the present circumstances specialists will not only be released months after general-duty medical officers, but will also suffer a considerable delay as compared with ordinary combatant officers. It is appreciated that there must inevitably be unevenness in the pace of release in different categories of the Services, but we feel that insufficient effort is being made by the Central and Local Medical War Committees to recruit specialist replacements. Our experience of recent "short lists" suggests that a considerable number of candidates of military age have never had war service, and it would seem unfair that such people should not only have escaped war service but should be successful in obtaining specialist appointments in view of their unbroken civilian service.

Considering the present dissatisfaction among specialists we wish to make the following recommendations: (1) That detailed lists of specialists who for medical or other reasons have as yet carried out no war service be made by Central and Local Medical War Committees. Where medical reasons have been responsible for exemptions or postponements these be revised in the light of the less exacting peacetime conditions. (2) That the responsible military authorities be urged (a) to revise their existing military establishments and thus limit their specialist requirements, and (b) to expedite the training of suitable regular Army officers to fill specialist deficiencies.—We are, etc.,

TWO SPECIALISTS.

Medical Unemployment

SIR,—I thoroughly endorse the remarks of "Unemployed Ex-Serviceman" and Dr. G. L. E. Thomas (Aug. 3, p. 58), and other returning or unemployed doctors in previous issues. It would be interesting to know how many of us are in this predicament. There are many to my knowledge, and some are beginning to look beyond medicine for a livelihood. This serious situation cannot be given too much emphasis and publicity.

After serving in the R.N.V.R. from Sept., 1939, to Feb., 1946, I got married on demobilization, and have since been living on steadily diminishing capital. Countless letters in reply to advertisements for assistants or partners have brought no reply, and those to business or industrial firms, or for other appointments, have brought the reply regretting that the vacancy has now been filled. It seems impossible to buy a suitable practice without involving oneself in debt for life in order to buy the house. Few of us expect any particular gratitude for our war service, but it must be known that most of us suffered financially, and the aftermath appears to be ruination.

It is astonishing to find speedier demobilization of Service M.O.s being urged. Those still in the Forces are more fortunate than they seem to imagine. Whilst sympathizing with those alien doctors still in this country, it does seem that our own people should be entitled to prior consideration. Most Service doctors were no more in favour of the National Health Service than were our colleagues at home, but now there must be few of us who do not anxiously await its advent at the earliest possible moment.—I am, etc.,

"EX-R.N.V.R."

Association Notices**CONSULTANTS AND SPECIALISTS COMMITTEE***Part-time Consultants and Specialists*

Notice is hereby given of the formation by the Council of an electoral roll for the election to the Consultants and Specialists Committee of five representatives of members of the Association who are engaged part-time in consultant and specialist practice. Members of the Association who claim to conform to this definition, including those serving with H.M. Forces, are requested to complete and return the appended form to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1, later than Monday, Sept. 2, 1946.

CHARLES HILL,
Secretary.

Aug. 3, 1946.

BRITISH MEDICAL ASSOCIATION**CONSULTANTS AND SPECIALISTS COMMITTEE**
*Part-time Consultants and Specialists***FORM OF APPLICATION FOR INCLUSION IN ELECTORAL ROLL**

To the Secretary,
British Medical Association,
B.M.A. House, Tavistock Square,
London, W.C.1.

I wish to apply for inclusion in the electoral roll for the election of representatives of part-time consultants and specialists on the Consultants and Specialists Committee. I am a member of the Association and am engaged part-time

in the consultant and specialist practice of.....

POSTGRADUATE NEWS

A special two weeks' postgraduate course in cardiology will be held at the Liverpool Heart Hospital (Oxford Street, Liverpool) from Monday to Friday, Sept. 16 to 20, and Monday to Friday, Sept. 23 to 27, at 3.30 p.m. and 4.30 p.m. each day. The fee for the course is £1 1s., and applications to join should be sent to the secretary of the hospital. Details will be published in the diary column of the *Supplement* for the appropriate weeks.

A series of postgraduate lectures will be given at the Victoria Hospital, Blackpool, on Thursdays, at 8 p.m., from Sept. 12 to Dec. 12, both dates inclusive. Details will be published in the diary column of the *Supplement* week by week.

Twelve lectures on "The Psychology of Delinquency," part of the University of London Extension Courses, will be given by Dr. Alan Maberly at the Institute for the Scientific Treatment of Delinquency (8, Bourdon Street, Davies Street, London, W.) on Wednesday, at 7 p.m., beginning on Oct. 2. The fee for the course is £1. Full details may be obtained from the general secretary of the institute.

A 14-day general refresher course will be held at Addenbrooke's Hospital, Cambridge, beginning on Monday, Oct. 14. The course is open to medical officers released from H.M. Forces and to national health insurance practitioners, who will receive the same allowance as are allowed to medical officers released from H.M. Forces. Further particulars and forms of entry may be obtained from Dr. A. C. D. Firth, Trinity Hall, Cambridge (Tel.: Cambridge 5047).

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Theatre Edinburgh Royal Infirmary, *Thurs.*, 4.30 p.m. Dr. J. D. S. Cameron, Treatment of Amoebiasis.

APPOINTMENTS

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—Visiting medical staff appointments. *Director of the Department of Radiology*, L. G. Blair, M.R.C.S., L.R.C.P., D.M.R.E. *Physician to Out-patients*, P. R. Evans, M.D., F.R.C.P. *Director of Department of Physical Medicine*, B. F. Kiernander, M.B., B.S., D.M.R.E. *Physician to Department of Psychological Medicine*, Eleanor M. Creak, M.D., D.P.M. *Dental Surgeon*, T. Craddock Henry, M.R.C.S., L.R.C.P., L.D.S. *Anaesthetists*, D. Aserman, M.D., D.A., B. G. B. Lucas, M.R.C.S., L.R.C.P., D.A.

CLARKE, H. OSMOND, F.R.C.S., Honorary Surgeon and Assistant Director of Orthopaedic and Accident Department, London Hospital.

DAVIDSON, J. ROMANES, M.D., Medical Superintendent, Orphan Homes for Scotland and Colony for Epileptics, Bridge of Weir, Renfrewshire.

HANNESON, HANNES, M.R.C.S., L.R.C.P., Medical Superintendent, Croydon County Borough Sanatorium, North Cheam, Surrey.

Branch and Division Meetings to be Held

ISLE OF WIGHT DIVISION.—At Nurses Home, Royal I.W. County Hospital, Ryde, Sunday, Aug. 25, 2.45 p.m., Combined Clinical and Medico-Political Meeting. Dr. Charles Hill: The Present Position. All practitioners are invited to attend.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BROWN.—On August 10, 1946, at Sutton Coldfield, to Jean, wife of Dr. J. W. Brown, a son.

CAGNEY.—On August 6, 1946, at Margate Maternity Home, to Mary (nd Darlow, M.B., Ch.B.), wife of D. J. Cagney, a son.

MURPHY.—On August 8, 1946, at 2, Trafalgar Avenue, S.E.15, to Doctor Edward Graham and Mary Patricia (née McHugh), a son.

OWSTON.—On August 7, 1946, at the Bromhead Maternity Home, Lincoln, to Ethel Winifred Owston, M.B., Ch.B. (née Sharrard), wife of Philip Owston B.Sc., a daughter—Winifred Joy.

MARRIAGES

GANGULI—BLACKMORE.—On July 14, 1940, at South Kensington, London. Amiya Nath Ganguli, M.B., B.S., D.C.H., to Mme. Violetta Blackmore.

HOWARTH—HOPKINS.—On July 16, 1946, at Llanid, Frank Hugo Howard M.A., M.B., B.Chir., Major, R.A.M.C., to Lucy Gwendoline Irene Hopkin

SPRIGGS—BUTLER.—On July 27, 1946, at St. Paul's, Wednesday, Richard Spriggs, Inspector, Somalia Gendarmerie, to Clarice Butler, M.B., Ch.B.

DEATHS

MORTON.—On August 7, 1946, at Kirkland, Berwick-on-Tweed, Colonel H. S. Murray Morton, C.B.E., D.S.O., R.A.M.C. (retired), dear husband of H. S. Morton.

NISSE.—On August 14, 1946, at 106, Teignmouth Road, Brondesbury, N.W., Bertram Sidney Nisse, M.D., M.R.C.P. Deeply mourned.

RAW.—On August 5, 1946, at Whitby, Yorkshire, Herbert Harland Raw, M.R.C.S., L.R.C.P., aged 68.

TOBACCO AND ULCER DYSPEPSIA*

BY

R. A. JAMIESON, F.R.C.S.

C. F. W. ILLINGWORTH, F.R.C.S.

AND

L. D. W. SCOTT, M.R.C.P.

It is a common practice to advise patients suffering from peptic ulcer to use less tobacco. This advice does not appear to rest on any secure basis, and it therefore seemed useful to find out if any relationship could be demonstrated between smoking habits and the severity of dyspepsia. The following observations form part of a follow-up survey of patients who had suffered acute perforation of a peptic ulcer from one to five years previously (Illingworth *et al.*, 1946). These patients were recalled for interview and were closely and persistently questioned. Our data are therefore as exact as we could make them. Of the 473 patients questioned 451 were men and 22 women. Their ages ranged from 20 to 64 years at the time of the follow-up; patients beyond these age limits were excluded, as their financial state might unduly influence their consumption of tobacco.

Two methods of inquiry were followed. First, we sought a relationship between the consumption of tobacco and the severity of symptoms during the twelvemonth prior to the follow-up. Secondly, we tried to determine if those patients who had reduced their tobacco consumption after perforation had less dyspepsia than those whose smoking was unchanged or increased.

Cigarette Smoking and Severity of Symptoms

Table I shows the relationship between cigarette consumption and the severity of symptoms during the twelvemonth before questioning.

TABLE I.—Number of Patients (aged 20–64 years) by Cigarette Consumption and by Severity of Symptoms

Severity of Symptoms	Cigarette Consumption per Day		
	0–10	11–20	21 or More
None	98 (84.3)	71 (78.3)	19 (25.4)
Mild	68 (71.3)	71 (66.2)	20 (21.5)
Severe	46 (56.4)	55 (52.5)	25 (17.1)

$\chi^2 = 10.82$, P less than 0.05.

The figures in parenthesis are the numbers of cases which would be expected if cigarette smoking were independent of the severity of symptoms. It is seen that more light smokers were symptom-free and more heavy smokers had severe symptoms than would occur if smoking and dyspepsia were unrelated. Statistical analysis shows that these differences would arise by chance less often than once in 20 such experiments, and it can be inferred that there is indeed a relationship between cigarette smoking and the severity of symptoms.

Pipe Smoking and Severity of Symptoms

Table II gives a comparison of the consumption of pipe tobacco and the severity of symptoms in the same way. It will be seen that the differences between the observed values and the expected values are to the advantage of the pipe smokers. Thus fewer non-smokers were symptom-free and more heavy

smokers were symptom-free than would be expected if there were no relationship between pipe smoking and severity of symptoms. The differences are not large, and statistical analysis shows that this result might occur by chance about once in 10 such experiments. It can be inferred that the evidence is suggestive of an association between pipe smoking and mildness of symptoms.

TABLE II.—Number of Patients (aged 20–64 years) by Consumption of Pipe Tobacco and by Severity of Symptoms

Severity of Symptoms	Pipe Tobacco Consumption per Week		
	None	1–2 oz. (28–56 g.)	3 oz. or more (85 g.)
None	159 (165.0)	13 (12.3)	16 (10.7)
Mild	139 (139.5)	11 (10.4)	9 (9.1)
Severe	117 (110.5)	7 (8.3)	2 (7.2)

$\chi^2 = 7.26$; P just exceeds 0.1.

These results are in sharp contrast. Heavy cigarette smoking seems to be associated with severe symptoms, but pipe smoking with mild symptoms. Tobacco, as such, can hardly be responsible for this finding. Several explanations could be offered: it might be that cigarettes are harmful because of the saltpetre they contain; or it might be that cigarette smokers differ in constitution from pipe smokers. We believe, however, that the correct explanation is the simple one that older patients tend to have mild symptoms and as a group comprise few cigarette smokers and many pipe smokers. The evidence on which these statements are made is given below.

FIG. 1.—Relationship between age and severity of symptoms in patients suffering perforation 1–5 years previously.

TABLE III.—Relationship between Age and Severity of Symptoms in Patients suffering Perforation 1–5 years previously (See Fig. 1)

Severity of Symptoms	Number of Patients		
	Age 20–34 years	Age 35–49 years	Age 50–64 years
None	45 (37.5)	74 (35.1)	69 (48.7)
Mild	39 (33.2)	70 (33.2)	50 (35.1)
Severe	35 (30.2)	66 (32.2)	24 (17.2)
Total	120 (100.0)	210 (100.0)	143 (100.0)

* This investigation was carried out under the auspices of a Committee on Sickness Records set up in Glasgow by the Nuffield Provincial Hospitals Trust.

It is seen from Fig. 1 and Table III that the symptoms in the group aged 50-64 years are milder than in the younger age groups. Thus 48% of the older patients are symptom-free, as against 35% of the younger, while only 17% of the older group have severe symptoms, as against 30% of the younger.

Again, it is seen from Fig. 2 and Table IV that cigarette consumption is less in the group aged 50-64 years than in the

FIG. 2.—Relationship between age and cigarette consumption in patients suffering perforation 1-5 years previously.

TABLE IV.—Relation between Age and Cigarette Consumption in Patients suffering Perforation 1-5 years previously (See Fig. 2)

Cigarettes per Day	Number of Patients		
	Age 20-34 years	Age 35-49 years	Age 50-64 years
-10	47 (39%)	85 (41%)	80 (56%)
-20	54 (45%)	97 (46%)	46 (32%)
21 or more	19 (16%)	28 (13%)	17 (12%)
Total	120 (100%)	210 (100%)	143 (100%)

younger age groups. Thus 56% of the older patients are light smokers, as against 40% of the younger, while only 32% of the older group are moderately heavy smokers, as against 45% of the younger.

TABLE V.—Relationship between Age and Pipe Smoking

Age	No. of Pipe Smokers
34 years	6 (among 120 patients)
39 "	20 " 210 "
44 "	32 " 143 "

Lastly, it is seen from Table V that the oldest group includes many pipe smokers, for no fewer than 32 of our total of 58 pipe smokers belong to the age group 50-64 years.

We conclude, therefore, that the relationship between smoking and dyspepsia is unlikely to be one of cause and effect; and we suggest that cigarette smokers tend to have severe symptoms because they are in the main young,* and that pipe smokers tend to have mild symptoms because they are in the main old.

Change in Smoking Habits and Severity of Dyspepsia

If smoking were harmful to patients with peptic ulceration, then it should be possible to show that better health is enjoyed by those who have reduced their tobacco consumption than by those whose smoking has been unchanged or increased. Tables VI and VII provide the data necessary for cigarette smokers and pipe smokers respectively. In these tables the severity of symptoms refers to the twelvemonth preceding examination, and the change in tobacco consumption refers to the difference between the consumption before perforation and that at the time of examination.

* We have verified that the data of Table I can be regarded as homogeneous if age is allowed for, thus: using the same classification for patients aged 20-49 years, $\chi^2 = 6.48$, P about 0.2; and for patients aged 50-64 years, $\chi^2 = 3.48$, P about 0.5; the combined value of $\chi^2 = 9.96$, P about 0.3.

TABLE VI.—Number of Patients (aged 20-64 years) by Change in Cigarette Consumption and by Severity of Symptoms

Severity of Symptoms	Cigarette Consumption		
	No Change	Increased at Follow-up	Decreased at Follow-up
None	124 (125.8)	17 (12.1)	47 (50.1)
Mild	104 (105.5)	10 (10.4)	45 (43.1)
Severe	85 (81.7)	4 (8.5)	37 (35.8)

$$\chi^2 = 4.88, P \text{ about } 0.3.$$

It is evident from Table VI that there is little difference between the observed numbers of patients and the numbers which would be expected if changes in cigarette consumption and severity of symptoms were unrelated, and statistical analysis indicates that this result might occur by chance once in every three such experiments.

TABLE VII.—Number of Patients (aged 20-64 years) by Change in Consumption of Pipe Tobacco and by Severity of Symptoms

Severity of Symptoms	Consumption of Pipe Tobacco		
	No Change	Increased at Follow-up	Decreased at Follow-up
None	169 (170.2)	7 (5.1)	12 (12.7)
Mild	143 (143.8)	3 (4.4)	13 (10.8)
Severe	116 (114.0)	3 (3.5)	7 (8.5)

$$\chi^2 = 3.44, P \text{ about } 0.5.$$

Table VII shows, in the same way, that there is no evidence that increased pipe smoking is harmful. The difference between the observed and the expected numbers could easily be the result of chance. It must, however, be conceded that the number of pipe smokers in the investigation is too small to carry conviction.

It can be concluded that neither in the case of cigarette smoking nor in the case of pipe smoking is there any evidence that changes in tobacco consumption influence the severity of symptoms.

Comment

We are aware of the possible criticism that our data are biased by self-selection, on the ground that patients with severe dyspepsia may smoke little while those who are symptom-free have nothing to restrain them from smoking as heavily as they wish. Self-selection of this kind (light smokers tending to be selected from among the severely dyspeptic, and heavy smokers from among the symptom-free) might obscure the relationship we set out to investigate.

However, the importance of self-selection is probably not great, for the following reasons:

(1) If self-selection were important, it would be reasonable to expect a non-homogeneous distribution in our tables, whereas it has been shown that the distribution is homogeneous when age is allowed for.

(2) In our tables dealing with alterations in tobacco consumption (Tables VI and VII) it will be seen that smoking habits are relatively stable. Thus the majority of patients either smoke as much as before perforation or remain non-smokers. Of the few who have indeed altered their smoking, there is no evidence that it is those with severe dyspepsia who are smoking less or those without dyspepsia who are smoking more.

Summary

A group of 473 patients who had suffered acute perforation of a peptic ulcer were recalled for examination and were closely questioned about their smoking habits.

Heavy cigarette smoking was associated with severe symptoms, but pipe smoking with mild symptoms. It is suggested that the relationship between smoking and severity of symptoms is indirect and depends upon age: symptoms tend to be severe in the young and mild in the old; and cigarette smokers are in the main young, while pipe smokers are in the main old.

There was no evidence that increases or decreases in tobacco consumption influenced the severity of symptoms.

ELECTRO-CONVULSION THERAPY IN 301 PATIENTS IN A GENERAL HOSPITAL*

WITH SPECIAL REFERENCE TO SELECTION OF CASES
AND RESPONSE TO TREATMENT

BY

DALTON E. SANDS, M.R.C.P.Ed., D.P.M.

Deputy Medical Superintendent, Sutton Emergency Hospital

In this country psychiatric patients have rarely been treated in general hospitals under exactly the same conditions as other medical or surgical cases. Some indication of the possibilities of this branch of psychiatry has been given already (Sands, 1943), and the results bear comparison with any in general medical wards (James, 1945). One of the chief methods of physical treatment employed—convulsion therapy—has been the subject of numerous reports during the last nine years. Most of these have been from the mental hospital point of view—concerned mainly with the results, risks, and technical modifications appropriate to the more severe states of psychotic depression. The majority of depressions in general hospital psychiatric wards are of a different pattern (see later), requiring an altered plan of treatment. Before treatment they need special attention to differential diagnosis for the elimination of all those conditions whose superficial resemblance enables them to be covered by the term “depression.” Excepting a few—e.g., Stockings, 1944; Frank, 1945—most publications discuss the effects of convulsion therapy with little regard for the wide range of conditions involved. Since only a section of the total range of depressive states can be specifically treated by convulsion therapy, errors are not infrequent, with aggravation of illness and waste of effort. The issue is further confused by the profuse descriptive terminology linked with varieties of depression. Labels such as melancholia, reactive or endogenous depression, psychotic, psychoneurotic, agitated, involutional, psychopathic, anxiety depression, etc., are some of those encountered.

Concerning the question of diagnosis, textbooks necessarily stress the characteristic qualities of each reaction type, and unwittingly one comes to expect the illness in “pure culture” as it were—e.g., either schizophrenic or depressed. In actuality, the patient usually presents no full-fledged symptom-complex running true to a particular reaction type. Like the human society of which he is an individual member he shows but one phase in the evolution of a process, even if a pathological one. In the early stages of the process several abnormal personality trends may be apparent, and in different situations and times differing impressions will be gained of what may ultimately prove to be the main diagnosis. Later, as the evolution of the illness proceeds, condensation of the clinical picture tends to occur, narrowing down to one rather obvious reaction type. Perusal of the early records of a chronic case will often demonstrate this process of diagnostic “purification,” the complicated and uncertain diagnosis of recent illness moving, sometimes regressing, towards the single pathological type. In all cases incapable of early recovery this process is going on in greater or lesser degree. It is essential to recognize it in order to understand many of the clinical effects of convulsion therapy in those early cases of a few weeks’ or months’ duration which are the special concern of this paper.

Depression in a mental hospital patient is generally characterized by radical personality change and considerable inaccessibility. The diagnostic field is covered, to a large extent, by manic-depressive, recurrent, and involutional types, depressed G.P.s, pre-senile and arteriosclerotic psychoses, and occasionally early schizophrenias. By contrast, the subjects of depression seen in the general hospital or out-patient department in an earlier or milder phase of the same pathological process retain more of their original personality and are more accessible; questions of certification infrequently arise, and socially all are treated on the same footing as medical or surgical patients. Table I shows the different trend in

diagnosis of the general hospital depressive states. Less than 25% can be diagnosed as “manic-depressive, involutional, or recurrent.” The majority either are simple, endogenous, or reactive states or are associated with neurotic or psychopathic complications. A few are pre-schizophrenic. Generally their personalities remain well preserved and questions of certification hardly arise. The response of these patients to convulsion therapy, while often as satisfactory as in the more advanced psychotic depression, soon showed the need for special care and some reorientation in diagnosis and case selection. In 1934 Lewis, writing on the less advanced forms of depressive illness at the Maudsley Hospital, said, “Pure syndromes and reaction types are less and less often found as more careful examination of the patient and his illness is made.” One of the consequences of such difficulties is that many of the cases admitted to military mental hospitals as depressive psychoses are often not psychotic but acute reactive neurotic disturbances (Stockings, 1944). Conversely, in a neurosis centre it is not uncommon to find cases admitted as neurotic proving to be less severe forms of psychotic depression, even allowing for those termed neurotic for administrative reasons. A similar situation prevails with civilians.

However, such apparent contradictions and multiple patterns of reaction are natural enough, remembering the possibilities of pathological and non-pathological variations in the personality; but from the therapeutic aspect it is imperative to decide which is the dominant pattern or personality deviation responsible for the maintenance of the patient’s illness and which are of secondary significance. The mere intensity of symptoms is no reliable guide. In deciding, we need, more than ever, all relevant knowledge of the personality prior to breakdown, and of the transition from normal to pathological responses. The practical importance of all this is seen when a few convulsions clarify the uncertain diagnosis rather too drastically. Instead of the usual remission there may be further depression, confusion, anxious or hysterical symptoms, incontinence, or no demonstrable effect at all—not because the method is useless, but through the psychiatrist failing to perceive the mental pathology of his patient. The truth is that in this direction treatment has outstripped diagnosis and is likely to be more accurate than the clinician in doubtful cases.

Owing to the frequent finding of neurosis and depression in the same patient and the intractable nature of the chronic neurotic, attempts have been made to treat the neuroses with electric convulsion therapy (E.C.T.). The literature on the subject is conflicting, and most of the results are by way of an appendix to larger series of figures for the psychoses. Moriarty and Weil (1943) quote 14 authors for 130 cases of all forms of neurosis, of whom 28% were classified recovered, 61% improved, and 11% not improved. They concluded that these results were encouraging, and stated that 10 out of 20 of their own cases remitted with the additional assistance of psychotherapy. They were of the opinion that the better appetite, sleep, and affective gain wrought by E.C.T. paved the way for subsequent psychotherapy. In 1945 the same authors quoted 42 unclassified neurotics treated by E.C.T. and psychotherapy; of these 38% remitted, 55% improved, and 7% were unchanged. Pacella and Barrera (1943) thought that metrazol made neurotic patients worse, especially the obsessional compulsive group, and emphasized the need for psychotherapy in patients given E.C.T. Osgood (1944) draws attention to the difference in opinion about the value of E.C.T. in neuroses, while Bennett (1943) reported on 11 E.C.T.-treated cases, all showing some improvement. Kalinowsky *et al.* (1944) believe that the usefulness of this treatment in psychoneurotic conditions is not yet established. Smith *et al.* (1943) regard the treatment as of doubtful value. Frank (1945) found the post-convulsive automatism of psychoneurotics and psychopaths to be dramatic, to be covered by amnesia, and to be an expression of subconscious memory material. He observed that this “catharsis” did not seem to help. The outstanding impressions from these reports are the poverty of the results compared with those usual in psychotic depression, and the stress laid on the use of psychotherapy in the few favourable reports—a contrast to the perfunctory allusions to psychotherapy in discussing E.C.T. in psychotic depression.

* Patients were accommodated in one ward, sometimes two, of the general hospital block, separate from the military neurosis unit.

From the many varieties of mental disorder encountered at a neurosis centre I have selected 301 cases treated by myself or my colleague Dr. Shorvon with convulsion therapy, composed of neuroses (80), minor psychotic depression (134), and some having elements of both (87).

TABLE I.—Incidence

	%	No.
Minor psychotic depression:		
Simple endogenous	30.8	68
Reactive	7.2	16
Recurrent	8.1	18
Manic-depressive	5.0	11
Involutional	9.6	21
Depression with neurosis:		
Anxiety	9.6	21
Hysteria	13.1	29
Obsessional	9.0	20
Depression with depersonalization	3.1	7
Depression with psychopathic personality	4.5	10
Total depressions		221
Neuroses:		
Anxiety	35.0	28
Hysteria	37.5	30
Obsessional	27.5	22
Total (all cases)		301

The chief features of this sample of patients are: (a) They are representative of the largest section of psychiatric practice. For every major psychosis there are many of the above minor types. (b) Neurotic symptoms occurred to a greater or lesser degree in half the total number. (c) Genuine manic-depressive types were uncommon, but short-term emotional instability was relatively frequent. (d) Depression was often associated with psychosomatic, depersonalization, or psychopathic symptoms. Though listed as a leading feature of only 7 patients, depersonalization was a complication to some degree in at least 21 others. (e) The response to E.C.T. tends to be more variable than in the severer psychotic states seen in mental hospitals owing to the association of other reaction types with depression. The main clinical groups react to convulsions in an individual way that is often of assistance in diagnosis—more so than earlier reports led one to expect.

Primary Neurotic States

1. Obsessional Neurosis.—Since the use of convulsion therapy the treatment and prognosis of this group depend more than ever on deciding whether the depressive aspect of such patients represents the primary factor in a psychotic depression or a secondary one in a severe obsessional neurosis. A full psychiatric examination will settle the matter in many instances, but psychiatrists will be familiar with the intermediate type in which the relative proportion of obsessional neurosis and depression cannot be definitely assessed. The mere intensity of such obsessional or depressive symptomatology as the patient displays is no reliable guide, for patients tend to insist on the primary nature of the obsession (Lewis, 1934). Their misleading insistence has led to unjustifiable claims for the successful treatment of obsessional neurosis by E.C.T. The following example from a case in this series originally diagnosed as obsessional neurosis illustrates the difficulty. The patient presented strong obsessional symptoms of 16 years' duration. Her father and one brother had obsessional personalities. Her condition was such that four experienced psychiatrists considered her suitable for leucotomy and unlikely to respond to E.C.T. None the less, she improved so much on a course of convulsions that after receiving six she was discharged and shortly returned to work. It may be objected that a more carefully taken history would have elicited a point in the illness where depression set in, but it could not be found even where a predisposition to do so existed. She partly relapsed after a year. Table II shows the results of treatment in two groups of neurotic and psychotic patients, both having strong obsessional compulsive thoughts.

The disparity in results is obvious. Only 3 obsessional neurotics showed much improvement, compared with 17 out of 20 cases of obsessional depression recovered or much improved. Besides depression, four of the obsessional neurosis cases were complicated by anxiety and two by schizophrenic

features. The follow-up finding that 5 out of 13 cases of obsessional neurosis could be considered recovered after twelve months is in agreement with those who believe that this form of neurosis has a less gloomy prognosis than is often thought to be the case. The effect of convulsion therapy on obsessional

After 12 months ..	5	3	3	1	1	13	4	4	0	0	0	8

R = Recovered. MI = Much improved. I = Improved. NC = No change. CR = Complete relapse.

neurosis was usually negligible. After 6 to 8 convulsion amnesia may lead to a temporary "sham" recovery. Some times a symptomatic improvement occurred for 12 to 24 hours after a fit. This temporary breaking up of the obsessional pattern occasionally paved the way for progress in psychotherapy—the combined treatment resulting in a better adaptation. Apart from early complaint of memory defect, the obsessional neurotic was singularly free from the mental complications seen in other types, to be discussed shortly.

TABLE III

	Anxiety Neurosis						Depression with Anxiety					
	R	MI	I	NC	CR	Total	R	MI	I	NC	CR	Total
At discharge ..	1	5	11	11	0	28	10	6	4	1	0	21

After 12 months ..	2	3	5	3	5	18	10	3	2	1	1	17

2. Anxiety Neurosis.—Of the 28 cases of anxiety neurosis listed in Table III 19 were associated with varying degrees of depression, 7 with obsessional symptoms, 6 with hysteria and 3 with depersonalization. The distinguishing features of their reaction to E.C.T. are: (a) more apprehension before treatment than any other group, treatment often becoming a focal point in their phobias; (b) exaggeration of somatic symptoms appears for a few hours or days. Aches and pains of a vague psychogenic quality occur in various parts of the body, and there is much unattached fear. These developments indicate that treatment should be stopped if the patient has not already refused to continue. There is every likelihood of doing more harm than good in attempting to treat anxiety states with E.C.T., and the contrasted results of Table III are obvious enough.

TABLE IV

	Hysterical Neuroses						Depression with Hysteria					
	R	MI	I	NC	CR	Total	R	MI	I	NC	CR	Total

After 12 months ..	3	2	6	9	0	20	5	8	4	2	5	24

3. Hysteria.—In the 30 patients of this group conversion symptoms were sometimes present, but were not of a fully developed or fixed type. The majority showed some superficial depression, and the prognosis in general was poor. There were two forms of reaction to E.C.T.—a dramatic but transient improvement, and, more often, a flare-up of psychological and physical symptoms. Any new physical discomfort provoked by the treatment tends to be incorporated into the hysterical pattern. For example, slight nausea will tie them to a bowl for an hour or more in expectation of vomiting if allowed to do so, though in all other patients the liability to vomiting is rare in E.C.T. Similarly, old-standing hysterical pains such as backache become greatly exaggerated. It is true to say that such improvement as occurred in these hysterical neurotics was due to other treatment or could be ascribed to wrong diagnosis.

So far as primarily neurotic illness is concerned one can only conclude that convulsion treatment is best avoided. Neurotic patients complain of memory defect much earlier

id more insistently than do psychotics. In anxious or hysterical conditions the patient may be made temporarily worse. The effects of E.C.T. are not comparable with those of psychotherapy in neurosis, where Curran (1937) has reported definite improvement in from 60 to 70% of patients. Where complexity of psychotic and neurotic traits defies ordinary means of diagnosis it may sometimes be justifiable to employ a few well-spaced convulsions to give further information for the purpose of taking a more definite line in treatment.

Depression with Neurotic Complications

In this section the same personality deviations are considered—i.e., depression, hysteria, anxiety, and obsession states—but their relative importance in the aetiology is reversed. In these patients the principal reaction type is mild or moderately severe psychotic depression, while neurotic symptoms are of secondary aetiological importance. The latter were definitely present in one-third of the 221 cases. To a degree which depends on their development in the previous personality, these neurotic symptoms modify prognosis and treatment in their own characteristic way. When they are the outcome of comparatively minor neurotic traits in an otherwise well-adjusted personality they disappear as the depression is benefited by treatment. Alternatively, the more closely neurotic utilities in the previous mental make-up approach the status of chronic symptoms the less satisfactory will be the final effect of E.C.T. on an intercurrent psychotic depression.

Accurate information about the previous personality of a patient suffering from depression and neurotic symptoms will enable one to forecast the extent of recovery after treatment. If the previous personality has been well adjusted, having no more than mild neurotic trends, then the depression and neurotic symptoms, however florid, are likely to respond to treatment. But if the personality has been definitely handicapped for a long time by neurotic features; then, though the depression may remit, the neurotic symptoms will subside only to persist at their former level in the personality. Although an infinite variation prevails in the ratio of psychotic to neurotic activity, we must endeavour to decide which is the dominant pathological deviation. Failure in this respect may leave the illness not merely unchanged but worse after E.C.T., as already noted.

Obsessional symptoms are the only neurotic complication having any favourable effect on the outcome of a psychotic type of depression. The immediate results are as satisfactory as in uncomplicated depression; patients were not prone to the mental complications seen in other neuroses, and the relapse rate was the lowest for any of the larger clinical groups. These last two factors are no doubt a corollary to the rigidity usually imposed on the personality by obsessional qualities, and recall the influence of the obsessional mechanism in preserving the personality of the schizophrenic patient (Stengel, 1945). Subjects with depression complicated by neurosis complain of memory defect earlier and more often than purely psychotic types. Obsessional depressive patients notice this forgetfulness more than any other group treated by E.C.T.

Where recent anxiety symptoms complicate depression they do not materially affect the result. Such patients are more apprehensive of E.C.T. and may need premedication. Sodium amytal 3 to 6 gr. (0.2 to 0.4 g.) half an hour before treatment, or 3 ml. of 10% sodium amytal intravenously immediately beforehand, will not prevent the fit, though a small voltage increase is sometimes required. This modification is also useful for temporary post-convulsion restlessness or excitement.

The presence of hysterical symptoms in a case of depression means a more unstable constitution. In 29 patients of this type 9 had partly or completely relapsed in six months, and 12 in a year. Immediate results compared unfavourably with other depressive states with or without neurosis, so that this was the only group in which recovered cases were exceeded by any less satisfactory category. Even so, the contrast with the primary hysterics in results is very striking. This contrast is most obvious in Tables II and III, and one is tempted to infer that where a case considered to be primarily neurotic has shown considerable gain with E.C.T. the diagnosis is probably wrong.

The depressions with secondary neurotic symptoms, having a combined "recovered-much improved" rate of 76.5%, compared well with 77% for all other depressions shown in Table V.

TABLE V.—Depressions (Endogenous, Reactive, Involutional, Recurrent, Manic-depressive, and Psychopathic)

	R	MI	I	NC	CR	Total
On discharge ..	59 (54%)	25 (23%)	20 (18%)	5 (5%)	0 (0%)	109
After 6 months ..	41 (45%)	20 (22%)	20 (22%)	1 (1%)	9 (10%)	91
After 12 months ..	44 (60%)	12 (16%)	9 (12%)	4 (6%)	4 (6%)	73

The results in these mild or moderately severe psychotic cases differ little from other published reports. Their condition, on discharge, of 77% recovered and much improved, 18% improved, and 5% unchanged, is in keeping with the 47 statistical reports collected by Ziskind *et al.* (1945), in which 2,777 cases were divided into 69% recovered and much improved, 18% improved, and 13% unchanged. One patient committed suicide three months after discharge.

Relapses

Since relapse is sometimes considered to be frequent, its incidence was fully examined, and is shown in Table VI.

TABLE VI.—Relapses (6 months to 4 years)

	No. of Patients	Partial Relapse	Complete Relapse	Total Relapsed
Depression:				
Endogenous ..	68	7 (10.3%)	8 (11.7%)	15 (22%)
Reactive ..	16	0 (0%)	4 (25%)	4 (25%)
Recurrent ..	13	9 (50%)	3 (16.6%)	12 (66%)
Involutional ..	21	2 (9.5%)	4 (19%)	6 (28.5%)
Manic-depressive ..	11	1 (9%)	1 (9%)	2 (18%)
Psychopathic personality ..	10	0 (0%)	0 (0%)	0 (0%)
Anxiety ..	21	4 (19%)	3 (14.3%)	7 (33.3%)
Hysteria ..	29	7 (24%)	5 (17.2%)	12 (41.3%)
Obsession ..	20	2 (10%)	1 (5%)	3 (15%)
Depersonalization ..	7	1 (14.3%)	2 (28.5%)	3 (42.8%)
Total ..	221	33 (14.9%)	31 (14%)	64 (28.9%)

Of all relapses, half occurred within the first 6 months, approximately a quarter more within a year, and the remaining quarter within four years. If out-patient observation is maintained for six weeks after discharge many incipient relapses can be curtailed by further treatment. The 25% relapse rate for reactive depression is misleading if one does not allow for the fact that the personal problems of all the patients represented in the percentage could not be appreciably alleviated, and demanded an exceptionally high degree of adjustment. The unfavourable effect of neurotic features on the incidence of relapse has been noted elsewhere, obsessional depressions excepted. The high relapse rate of the recurrent group offers no hope of convulsion treatment limiting their constitutional liability to subsequent attacks. The case with which these recurrent cases become depressed is usually paralleled by their rapid response to a few fits. Remembering that all these patients were subject to frequent bombing and other wartime stresses, the general relapse rate is probably not excessive. In the largest single group of endogenous depression only one out of every eleven relapsed completely.

Indifferent Results

To assist in case selection 52 depressed patients discharged "improved" or with "no change" were examined for factors which might have contributed to these unsatisfactory results.

(1) *Treatment was insufficient* in 14 cases on account of physical handicaps, refusal to complete the course, or the presence of strong delusional symptoms in the depression. In the latter cases, as Fitzgerald (1943) has pointed out, longer courses of fits are necessary than in simple depressions. Of the 5 cases of depression which made no improvement at all (see Table V) 4 had insufficient treatment owing to premature discharge. Of the 23 patients listed as "improved" 5 failed to complete their treatment, while no such failures were seen in the "recovered" and "much improved" categories.

(2) In 20 depressed patients severe chronic neurotic symptoms with hypochondriasis and depersonalization prevented full recovery. Such symptoms persisted even though depression was improved.

(3) *Psychopathic personalities* adversely affected progress in at least 5 cases.

(4) In 4 cases an early depression proved to be a temporary mask for *schizophrenia*.

(5) In 7 cases *persisting reactive stresses* remained undisclosed until several fits had been given. Such patients would improve for 12 to 24 hours, then relapse. This type of response should always suggest further search for reactive factors, such as homosexuality, marital infidelity, etc.

(6) *Over-treatment*.—In one of my cases two fits were enough to translate depression into mania. In a general hospital psychiatric ward such a complication is an impossible problem which may result in transfer to an observation ward, unless the attack is mild enough to be well controlled by a course of continuous sleep. The first sign of such a change is failure to sleep, so that in cyclothymic patients it is well worth while maintaining a sleep chart each night to give the first warning of the manic swing.

In the whole series other factors prejudicial to full recovery were:

(7) *Subshock*.—In 66 depressed cases which had one or more subshocks in their course the recovery rate on discharge was 21% less than that for the whole series. Although it is generally considered advisable to use the minimum current which will induce a fit, it is probably better to give 10 to 15 volts in excess of the minimum rather than strive for a margin so narrow that there is substantial liability to subshock.

(8) *Age*.—In 220 depressed cases there was no significant variation for age until after 60, when the expectation of recovery or considerable improvement with E.C.T. is half the corresponding rate for early or middle life.

TABLE VII.—Results According to Age Groups

Age (years):	Under 20	21-30	31-40	41-50	51-60	61-70
A. Recovered and much improved	10	47	42	35	21	4
B. Improved and no change	3	19	15	12	9	3
Ratio of A to B	3.3	2.5	2.8	2.9	2.3	1.3

Depersonalization

This fascinating symptom, of which so little is really known, was prominent in 20 cases, and occurred in a lesser degree in many others. So long as it occurs in an essentially depressive setting, it will clear as the depression responds to E.C.T., and in this respect depersonalization behaves like any of the classical forms of neurosis. Where severe it has an unfortunate habit of clouding the depression. The patients tend to make it their chief complaint, and the real diagnosis is obscured. Combined "recovered" and "much improved" percentage depressed depersonalization cases is not significantly less than the corresponding figures for endogenous depression.

There remain a few points on which, as a result of further experience, it is possible to write more conclusively.

The Correct Number of Fits

There can be no absolute rule about this, since the number has to be adapted according to the type of illness and its severity in each patient. Because individual requirements may vary from 2 to 15 fits at the rate of one, two, or three a week, it is inappropriate to think in terms of set courses after the practice of injections of arsenobenzol for syphilis. As a rule, schizophrenic cases require from 10 to 15 fits at the rate of three per week, dropping to two after the first two weeks. For most depressions a frequency of two fits a week is sufficient. When delusional symptoms are prominent (cf. Fitzgerald, 1943) a total of 8 to 12 fits is usually needed, while in depressions not so complicated the number may range from 2 to 8. The latter figure is suitable for some chronic obsessional states. In many cases it is better to give fits more frequently at first and space them out later, according to progress. The above numbers are based on the practice of giving one or two further fits after remission of symptoms has occurred, in order to minimize possibilities of relapse. In general, the more often fits are given per week the greater the incidence of confusional states, of forgetfulness, and of delta activity in the E.E.G. pattern. The number cannot be properly regulated and the above complications minimized without personal interviews after every one or two fits, because

individual needs cannot be foreseen more than one or two treatments ahead. The patient should be interviewed on day when no treatment is given, otherwise apprehension and mild confusion after the fit render co-operation doubtful.

Fractures; Pregnancy; Late Fits

The symptomless character of most of the compression spine fractures occurring after E.C.T., the absence of subsequent disability after over 10 years, and the finding of similar fractures in 10% of epileptics (Cook and Sands, 1941) have allayed much of the anxiety felt in the matter. Since it is obviously desirable to minimize the chances of these fractures, the effect of extension over a rolled blanket placed under the mid-thoracic spine while counter-pressure is exerted on shoulders and hips, as recommended by Furst (1940), was tried on 100 female patients. Fracture boards were placed under the mattress. The incidence of fractures was reduced to 4%, compared with the 14.7% noted in 1941 (Cook and Sands), when no restraint was used in a group of 143 cases, half male and half female. With the spine fully extended only minor degrees of compression were found in the 100 patients so damaged. All patients were radiographed before and after treatment. In some reports pain in the back has been the criterion for the use of x rays and the basis for subsequent figures of fracture incidence. This is misleading since the pain is sometimes of purely muscular origin in many spinal fractures of the simple compression variety due to fits are not accompanied by pain. Local tenderness over the site of fracture, with or without pain referred round the lower chest towards the epigastrium, aggravated by deep breathing and coughing, is the most trustworthy clinical sign. In the present series of 301 patients an impacted fracture of the humeral neck was the only other form of bony complication.

One patient was discovered to be three months pregnant during a course of 5 convulsive shocks. Another was known to be pregnant until her course of 8 convulsions had been concluded. Both pregnancies subsequently terminated in full-time healthy children.

No late fits suggestive of induction of an epileptic habit are known to have occurred in this group, in spite of a fairly comprehensive follow-up, nor was there any evidence of lowered threshold for the induction of fits in the later stages of a course. The E.E.G. abnormalities in a group of 100 patients examined by Dr. Denis Hill did not include the characteristic wave and spike of petit mal.

Commentary

One of the most interesting points about convulsion therapy is the consistency of its effects amongst the commoner mental illnesses, with the resulting illumination of diagnosis in doubtful cases. First, as between neurotic and psychotic states: although symptoms of both may often be found together, early cases, if convulsion therapy is given, it differentiates between them and emphasizes the gulf between their appropriate treatment. While the psychotic depression cases, with the withdrawal from reality and diminished awareness of the environment, thrive on the massive psychological and physical stimulus of the fit, the neurotics, with a pathological awareness of self and unstable and exaggerated emotional response to environmental change, are aggravated by such trauma. The results here and in other papers support this view. In the psychotic group itself (organic cases excluded) the efficiency of the treatment shows considerable variation, depending largely on whether affective or thought disorders predominate. Though results in the former are generally good, the latter do not show the same immediate specific response. Those conditions regarded as primarily disorders of thought—namely, the schizophrenias, paraphrenias, and paranoidias—have their own mode of reaction. There is usually no detectable response until 4 to 6 fits have been given; then some symptomatic improvement occurs coincident with forgetfulness of recent events, with mild confusion, and with dysrhythmia in the E.E.G. If the treatment is continued further, as advocated by some authorities, then after 10 to 15 fits appears the plateau type of over-politeness and emotional shallowness described by Frank (1945). In fact, a temporary sharp

improvement is maintained so long as some degree of disintegration of pattern of thought can be effected by the fits. Individual cases have often done well, particularly where a lively affective reaction accompanies schizophrenic thinking. Even so, as Sargant and Slater (1944) have pointed out, relief of the mood disorder may occur, leaving a pathological thought content uninfluenced. It is hardly surprising, therefore, that figures for large series of such patients are not to be compared with results in depressions, and in the long run are not better than those in controls. By contrast, in psychotic depression the patient may have recovered, or be well on the way to doing so, before discoverable abnormality of memory or E.E.G. can be found. Old people often respond well to E.C.T., although about the age of 60 or later it is not uncommonly found that, after dispersal of depression, senile changes remain in the form of narrowness and poverty of ideation, tendency to perseveration, and the use of a very limited range of words. In mania the effect is less dramatic, yet E.C.T. appears to exert a form of sedation on the manic symptoms, often most useful at the height of the illness. Neuroses, depressions with neurotic features, and reactive depressions have all been described as possessing characteristic reactions to convulsion therapy. It is certain that the careful observation of these reactions under in-patient conditions can give much useful information about the underlying psychopathology, duration of treatment, and prognosis—the very part of the treatment requiring a specialist's attention.

TABLE VIII.—Case Selection for E.C.T.

Favourable	Doubtful	Contraindicated
Psychotic depression with retardation, agitation, delusions, and neurotic or psychopathic complications	Schizophrenia	Anxiety neurosis
Depressed phase of manic-depressive psychosis	Paraphrenia	Hysteria
Recurrent depression	Paranoia	Neurasthenia
Involutional depression	Obsessional neurosis	Organic psychoses with syphilis or with arteriosclerosis
Reactive depression where reactive stress has faded	Idiopathic epilepsy	Pre-senile dementia
	Post-encephalitic	Post-traumatic syndromes
	Parkinsonism	Huntington's chorea
	with depression	

Regarding the whole problem of mode of action, it is difficult to escape the conclusion that a varying degree of personality disintegration and regression is required, sufficient to disorganize the recently acquired habits of feeling and thinking. The personality then employs long-established reflexes and patterns of behaviour to readjust at a slightly lower level, but not necessarily to stay there. Concerning the far more drastic procedure of leucotomy, Golla (1943) recalled the work of Sherrington and Graham Brown demonstrating the remarkable recuperative powers of even the severely damaged nervous system. Similarly, in the few weeks immediately following convulsion therapy this inherent recovery process is paralleled by a gradual disappearance of forgetfulness and of such dysrhythmia as was engendered in the E.E.G. Such a process could hardly be expected to flourish in the presence of a pre-existing organic cerebral pathology; and in fact, if a case of depression secondary to arteriosclerosis, syphilis, or pre-senile dementia is inadvertently given E.C.T. the usual recuperation is impeded or absent. In such cases not only may a permanent state of regression be inflicted but the organic deterioration may be accelerated. Incontinence of urine sometimes gives an early warning of this error.

The propriety of using psychotherapy with E.C.T. in depression has often been discussed (Moriarty and Weil, 1943; Osgood, 1944). It depends on the type of depression and how far it has progressed. Moderate psychotic depressions, such as can be treated under general hospital conditions or as voluntary cases, are frequently blended with neurotic complications. If treated by E.C.T. the psychotic depression clears and the relief may enable the neurotic element to make a spontaneous adjustment. If it does not, then psychotherapy is indicated, being often assisted by the previous dispersal of the depressive element of the illness. Selinski (1943) and Kalinowsky *et al.* (1944) have commented on the better accessibility to psychotherapy given to some patients by E.C.T. In this respect, severe certified depressions are no problem, since, obviously, strict psychotherapeutic techniques cannot be applied to an inaccessible patient, while in depression secondary to a

primary neurotic disorder E.C.T. is certainly to be avoided in favour of psychotherapy. These methods are complementary, and inadequate treatment is inevitable if all therapeutic effort is canalized in one or other direction for every case.

A final point should be made about the relation of E.C.T. and other physical treatment to terminology. There is a tendency to associate the term "psychotic" too exclusively with mental hospital types. It is sometimes overlooked that there are at least as many cases of psychotic-type depression outside such hospitals whose treatment is equally urgent—and more so, since they are usually without proper observation and exposed to suicidal risks. In some a well-integrated personality can survive the stress of a mild psychotic depression, while in others the relatively sound integration may conceal severe symptoms even from those in closest contact, so that the final tragedy surprises all concerned. These patients respond well to E.C.T., and give results comparable to any in general medicine; none the less, these findings should deter the inexperienced but enthusiastic therapist from "pressing the button" without a satisfactory preliminary investigation of those appearing to be depressed, otherwise definite harm may be done to the patient. Repeated careful psychiatric examination before, during, and after treatment is the most important aspect of convulsion therapy—more so than the careful management of the actual fits.

I should like to thank Dr. H. J. Shorvon particularly for his co-operation in the treatment of the patients, Dr. W. Sargant for his helpful criticism and advice, and Dr. L. Minski for permission to publish the case material of this paper.

TECHNIQUE FOR THE USE OF d-TUBOCURARINE CHLORIDE WITH BALANCED ANAESTHESIA

BY

T. CECIL GRAY, M.B., Ch.B., D.A.

AND

JOHN HALTON, M.B., Ch.B., D.A.

(From the Department of Surgery, University of Liverpool)

The novelty of curare has passed, and the site of action, physiology, and pharmacology of the drug have been the subjects of many recent publications (see Gray and Halton, 1946). It is thought that a description of the methods employed in the administration of d-tubocurarine chloride (B. W. & Co.) in some 1,500 cases might be opportune. For the sake of brevity in the ensuing discussion d-tubocurarine chloride (B. W. & Co.) will be referred to as curarine.

Apparatus

Solutions of curarine and the quick-acting intravenous barbiturates are non-miscible. It is necessary here to correct a misunderstanding that may have arisen through a previous statement that curarine dissolves in excess pentothal solution. This is perfectly correct when applied to the pure crystalline powder. However, the solution now supplied by the makers

contains a harmless stabilizing agent which renders irreversible the precipitate formed with the barbiturates. To overcome this precipitation and to ensure that the intravenous needle will remain clear, in position, and under control during the operation three pieces of apparatus are suggested for use in the techniques described below:

1. A simple on-and-off tap (Fig. 1) with Record mountings. (Obtainable from M. & I. E. & Co., Ltd., London.)

FIG. 1

2. A three-way tap mounted on a plate which can be strapped to the arm (Fig. 2). The tap itself may be detached from the plate for purposes of sterilization. One inlet is connected to an intravenous drip of saline, plasma, or blood. A Record syringe containing the solution to be injected is connected to the other inlet.

FIG. 2

The outlet is attached to two inches of fine-bore, transparent Portex tubing, which in turn leads to the needle (obtainable from Alexander Fowler & Co., Ltd., Liverpool).

3. The remote-control tap is described elsewhere by Gray and Osborne (1946)—a rather more elaborate method but having the advantage of ensuring perfect control with the arm in any position.

Premedication

Very light premedication is advocated. In these days of venous induction of anaesthesia there is no necessity for heavy sedation, and the respiratory depression it produces is harmful. For adults morphine gr. 1/6 (11 mg.) with atropine gr. 1/150–1/100 (0.4–0.65 mg.) has been the routine, but this is modified where age or the condition of the patient so demands. It has been found useful to substitute dilaudid gr. 1/32 (2 mg.) or pethidine 50–100 mg. when there is a history of excessive vomiting after previous anaesthesia. The time of administration of the pre-operative drugs is all-important: they should be given 1–1½ hours before the operation starts.

Technique of Administration for Short Procedures

This anaesthesia is suitable for all endoscopic investigations, but particularly for bronchoscopy and oesophagoscopy by virtue of the complete relaxation of the vocal cords and the pharyngeal sphincter. It is also of value in the re-suture of burst abdominal wounds. A single injection of 15 mg. of curarine is followed by a suitable dose of barbiturate, both given intravenously. In all cases under review 0.5 g. of pentothal or 0.75 g. of "kemithal" (Macintosh and Scott, 1946; Gordon and Gibbons, 1946; Halton, 1946) have been used initially.

The simple tap described above (Fig. 1) is connected to a needle size 15. A tourniquet is applied round the selected arm and venepuncture performed with the tap in the "off" position. Entry into the vein is confirmed by a reflux of blood when the tap is turned on. The tourniquet is released and three successive injections made: 1.5 ml. of curarine solution, followed by 2–3 ml. of sterile normal saline to wash through

the tap and the needle, and finally the barbiturate solution which should be given as quickly as the bore of the needle the syringe permit, the whole manoeuvre to be carried out clearly and speedily.

Satisfactory anaesthesia, indicated by complete relaxation of the jaw, speedily ensues. The pulse rate and respiration be under constant observation. The respiration ceases for 30 seconds to one minute and a half, but is usually restored before any degree of cyanosis or harmful anoxia can develop. Oxygen must always be administered. This is most easily through the side-tube on a bronchoscope, through a cat introduced into the trachea in the case of oesophagoscopy in other cases through a pharyngeal airway. At any cyanosis must be countered by the immediate institution of "aided respiration," described later.

The above dosage is applicable to adults of average age and in fair condition. In elderly patients there must be proportional reduction in dosage, and in children the dosage of curarine solution is 0.2 ml. (2 mg.) per stone (6.4 body weight). After doses of this order patients usually retain their protective reflexes and have full respiratory function seven to ten minutes; but should this not occur they are retained in the theatre until there is no fear of respiratory obstruction or depression.

Technique of Administration for Longer Procedures

This is essentially a balanced anaesthesia. After induction the patient is maintained in a light plane by means of an intravenous barbiturate. The curarine produces relaxation at the same time so reduces the amount of the barbiturate which has to be used that there is no delay in recovery. The addition of any of the inhalational agents is possible without causing laryngeal spasm. Their addition is useful when excessive manipulation or other factors arising during the operation demand a momentary deepening of the anaesthetic. Only minimal amounts of these agents are ever required. For very little experience the quantity of the barbiturate, curarine, and the inhalational anaesthetic can be so estimated that no excessive amounts of any single one of them produce a delay in post-operative recovery.

Control of respiratory exchange is essential in order to ensure that oxygenation is adequate and carbon dioxide elimination. This is best attained by use of a closed circuit. The circuit must be completely free from leaks, and the application of a mask to the face made really air-tight by packing gauze in the cheeks and the use of the Moreland Smith (1944) chin mask. When curarine is used in effective doses the tidal air is reduced. The inspiratory phase of the respiration must be amplified by rhythmic manual pressure on the re-breathing bag. This is "aided" rather than "controlled" respiration.

Adequate ventilation of the lungs is always possible through a pharyngeal airway of good design. Although endotracheal intubation under vision is simple when curarine is used, it is considered necessary only where the site and nature of the operation preclude the use of a mask, in thoracic operations when bronchial occlusion or suction drainage is required in cases of intestinal obstruction when there is a danger of regurgitation of abdominal contents. It is useful occasionally in operations on the gall-bladder in the very obese.

Dosage

The use of either the three-way tap or the remote-control device of Gray and Osborne greatly facilitates the repetition of intravenous injections required in these longer procedures.

Fifteen mg. of curarine are injected. When the patient is unable to keep his eyes open this is followed by either 0.5 g. of pentothal or 0.75 g. of "kemithal." After the lapse of a few minutes intubation under direct vision can be performed if necessary, or an airway can be inserted and the anaesthetic mask placed in position without cough or spasm. Before the skin incision is made 0.2–0.4 g. of pentothal or 0.4–0.8 g. of "kemithal" is injected, and in the case of abdominal operations this is fortified by 0.5–1.0 ml. (5–10 mg.) of curarine. When the case is one for thoracotomy the curarine is injected just before the opening of the pleural cavity. As a general

le slightly larger amounts will be required to control the diaphragm than will be found necessary in abdominal work. thoracoplasties curarine is used at induction, and again to control the diaphragm and excessive respiratory movements if apical mobilization is performed. During the operation slight movements or attempts at phonation, preceded by a rise in pulse rate, indicate the necessity for small increments of the barbiturate: these are in the nature of 0.1–0.2 g. of pentothal, or 0.2–0.4 g. of "kemithal."

A resistance to the inflation of the chest encountered by the end on the re-breathing bag is the first indication that more curarine is required. This is added in doses of 2–4 mg. It is commended that no curarine be given during the last twenty minutes of the operation, and the total dosage should not exceed 30–35 mg. The maximum amount of barbiturate that is used in long cases should not exceed 1.5 g. of pentothal or 5 g. of "kemithal." During the operation any approach to these maximal doses is anticipated, and a small amount of an inhalation agent, usually cyclopropane, is introduced into the circuit.

Experience has shown that this balanced technique results in far less post-operative morbidity than if the anaesthesia were either solely inhalational or solely intravenous.

Discussion

There is a rationale for the use of curarine. The drug should not be considered merely as an "aid" to anaesthesia, the last resort in a difficult administration; it is more—it is an integral part of the anaesthetic procedure. This is by virtue of four important properties: (a) it is quickly eliminated, leaving no toxic after-effects; (b) it produces relaxation as and when desired; (c) it abolishes laryngeal and bronchial spasm, making intubation of the trachea necessary only in selected types of cases; (d) because of the undoubted synergistic action with the anaesthetic agents the dose necessary to keep a patient asleep can be considerably reduced.

If these four properties are borne in mind, and if a correctly balanced anaesthesia is maintained, patients after long abdominal and thoracic operations are awake, in good vasomotor equilibrium, free from nausea, and able to exert their respiratory functions to the full. There is in consequence a smooth post-operative convalescence.

The drug may be given subcutaneously or intravenously. The first method need only be mentioned to be dismissed; it has no place in anaesthesia. When it is given intramuscularly the action is delayed for approximately fifteen minutes—often it is longer—and a maximum effect may not be seen for thirty minutes. It is obviously difficult to judge the injection so that relaxation will be present when and only when it is required. Furthermore, the duration of the action of the drug by this route is uncertain, especially when some degree of shock has reduced the absorptive functions of the circulation. In such cases there is a very great likelihood that the anaesthetist may be faced at the end of the operation with a patient whose respirations are laboured, who is unable to cough, and who is in urgent need of artificial respiration with oxygen. This is a very undesirable state of affairs, the proof of which lies in the proportion of post-operative chest complications seen when this technique is employed (Prescott, Organe, and Rowbotham, 1946). The same report advocated the use of an intravenous injection of curarine for induction with subsequent maintenance by the intramuscular route. This was tried early in the present series under discussion and abandoned for the reasons already given.

In conclusion, there are rare occasions when physostigmine, the physiological antidote to curarine, may be useful. It must be given in large doses and with atropine to prevent the undesirable parasympathomimetic effects. Prostigmin 3–5 mg. with atropine gr. 1/50 (1.3 mg.) has proved an effective combination.

There appear to be no real contraindications to the use of curarine provided that the administrator has a sound knowledge of the technique of its use and is familiar with the care of a patient in whom the usual signs of anaesthetic depth are absent, and where the natural process of respiratory exchange is impaired or completely abolished.

Summary

The technique of administration of *d*-tubocurarine chloride in some 1,500 cases is reviewed and the requisite apparatus described.

The rationale of its use is discussed and the various forms of parenteral administration assessed.

SOME USES OF THROMBIN IN THE SURGERY OF THE EAR, NOSE, AND THROAT

BY

PHILIP READING, M.S., F.R.C.S.

Surgeon, Aural Department, Guy's Hospital

In the surgery of the ear, nose, and throat many problems exercise the ingenuity and tax the patience of the surgeon. This paper is concerned with only two of these problems. The first is the control of bleeding, the second the healing of raw bony surfaces which have been deprived of their diseased covering by the removal of infected bone and granulations in the course of a radical mastoidectomy or similar operation.

Great reliance is commonly placed on the use of packing. Gauze is packed into one cavity to arrest bleeding; it is forced into another to control the overgrowth of granulations. Not only does the use of such a method frequently fail of its purpose, but also it favours continued infection and delay in healing. No evidence is needed of the discomfort such a gauze pack causes, or of the pain which its withdrawal inflicts.

The employment of thrombin enables the surgeon to dispense with packing in some situations where before it was essential. It is the purpose of this paper to indicate in what ways it can be so used.

Mellanby first prepared thrombin in 1933. The addition of thrombin to blood or plasma causes the formation of a clot. The ampoule in which it is supplied contains 5,000 Iowa units. One such unit is the amount of thrombin which will clot 1 ml. of standard fibrinogen solution in 15 seconds. With the ampoule containing the thrombin powder is another holding 5 ml. of sterile water, in which the thrombin powder is readily soluble. The rate of action of the thrombin can be varied by using more or less of the solvent. By using less solvent the surgeon obtains a fluid which clots plasma quicker than will a more dilute solution. It should never be injected into the tissues.

Control of Haemorrhage

The Throat.—Brisk arterial or venous bleeding does not respond to the action of thrombin (Ingraham and Bailey, 1944). Personal experience of its employment in tonsillectomy confirms this. An attempt was made to provide a firm clot in the tonsillar fossa by spraying the raw surfaces with thrombin solution after the larger vessels had been picked up and tied. This technique was followed in 166 tonsillectomies, but it did not, as had been hoped, prevent the occasional case of reactionary haemorrhage. Its use was therefore discontinued.

The Ear.—Thrombin has proved of great value in the control of oozing from small vessels. It is this bleeding which is such an embarrassment to the surgeon in the narrow field of the mastoidectomy wound. Constant oozing hides important bony landmarks, such as the torus of the external semicircular canal, and causes loss of time in the performance of the operation. After ligation of such vessels as can be picked up with a haemostat a few drops of the thrombin solution are run over the wound cavity. In a few moments a clot forms; this should be left undisturbed for 30 seconds or so. The outer layers of the clot can then be aspirated, leaving a fine film of clot over the whole surface.

* Thrombin, Topical, P.D., has been used in this series.

The Nose.—(a) Simple epistaxis is not easily controlled by the application of thrombin. A large unwieldy clot forms, and when this is detached fresh bleeding occurs. (b) After a submucous resection of the septum the two sheets of the nasal mucous membrane must be brought together to adhere, and so to obliterate the cavity left after removal of the distorted bone and cartilage. Usually both nasal fossae must be packed to keep these two sheets pressed together. By following the technique described below the need for packing can be avoided.

The operation is conducted under local analgesia, and consequently through a bloodless field. At the end of the operation the blades of a long Thudichum speculum are inserted between the two flaps of septal mucosa, and a few minims of thrombin solution are sprayed over the inner surfaces of the flaps. The speculum is withdrawn, and the blades, guarded with a few turns of moist gauze, are inserted on each side of the septum, thus pressing the mucous membranes together, when they will firmly adhere. The pressure need not be forcible, nor need it last more than a few seconds. If during the course of the operation the flaps have been accidentally torn, the edges of the tear can be spread in the position they should occupy. After moistening with thrombin, a short period of pressure will fix them in the desired position. No packing is left in the nose.

The contention that packing is necessary to keep the membranous septum straight is invalid. If the removal of bone has been adequately performed, the membranous septum will automatically assume a vertical position in the middle line. If the removal has been insufficient, no packing will correct the resulting deformity. Too much stress cannot be laid on the ill effects of nasal plugging. Even the most gentle packing inflicts abrasions upon this most vulnerable of membranes. By this technique damage to the ciliated epithelium is reduced to a minimum.

After the operation very little bleeding occurs; there is usually a blood-stained discharge for twelve hours. In only two of the 35 noses in which this method has been tried has bleeding been sufficient to call for post-operative packing in the ward. Reactionary swelling is very much less than when a pack has been employed, and the airway is consequently clear more quickly (Stevenson, 1944). Haematoma of the septum has not been seen.

Fixation of Skin Grafts by Means of Fibrin Clot

In performing a radical or modified radical mastoidectomy the surgeon aims at obtaining a smooth-walled bony cavity, lined throughout with skin, and possessing no recesses where infection may lurk and whence a troublesome discharge may subsequently issue. The achievement of this aim depends very largely upon the care with which all infected tissue is removed and upon the general shaping of the bony cavity. Only too often the surgeon's most meticulous care is wasted, as the cavity is left with hypertrophied granulations. These spring up and fuse with one another, so that there no longer exists one cavity, but several small pockets, separated by bands of organizing granulation tissue. Epithelization is delayed, sometimes indefinitely; and in spite of the most skilful and devoted after-care a surgical failure often results.

The introduction of the Thiersch graft was an important advance. If a skin graft can be persuaded to "take," the overgrowth of granulations is prevented and the interior of the mastoid cavity rapidly becomes covered with skin. Skin grafting is widely employed by aural surgeons, and to hold the graft in place the cavity is firmly packed with gauze or some other pressure dressing.

Split-thickness grafts of skin can be firmly fixed to their new beds by the precipitation of fibrin between the graft and its bed. This is brought about by the addition of thrombin to plasma. This technique has been employed in general surgery, and in the repair of extensively burnt areas, by Tidrick and Warner (1944), by Young (1944), and by Cronkite, Deaver, and Lozner (1944a, 1944b) amongst others. Young claims priority in the use of fibrin fixation alone without pressure dressings.

This method has been adapted to allow the fixation of skin grafts in the radical mastoidectomy cavity without the use of packing.

At the completion of the bony "exenteration," and of the cutting and suturing of the meatal plastic flap, great care is taken to secure haemostasis. The retroauricular wound is

sutured completely. A Thiersch graft is cut from a hairless area of the thigh. Bleeding from the donor area is stopped by running a little of the thrombin solution over it. The graft which should be about $1\frac{1}{2}$ by $1\frac{1}{2}$ in. (3.8 by 3.8 cm.) square is spread on tulle gras, raw side uppermost. Young states that washing the graft in saline removes coagulable elements from its surface, and no attempt should be made to wipe off any drops of blood or serum. The surface of the graft is the coated with plasma. This is the ordinary stock plasma of the "bank," and is sent up fresh on the day of the operation.

The graft is left to soak in the plasma while attention again turned to the mastoid cavity. All excess clot is removed by aspiration, and the interior is dusted lightly with a sulphuramide powder. Whatever powder is used, only the lightest dusting is permissible, as too much may act as a barrier to the early vascularization of the graft.

The skin graft and its attached tulle gras are cut into two or more pieces, depending upon the shape of the cavity to be covered. Before laying these grafts in place the excess of plasma is shaken off and a few minims of thrombin added both to them and to the surface of the bony cavity. The tailoring of these pieces of skin is admittedly difficult, but is made much easier than it would otherwise be by the fact that each piece can be stuck accurately in its allotted place like a postage stamp. A few moments' pressure with a narrow strip of gauze suffices to fix the graft in position, when the pressure can be relaxed and the gauze withdrawn. The process is then repeated with the next graft. Several small grafts are deliberately employed rather than a large one. A single graft lying in a complex cavity tends to fall into folds and creases, so that air spaces form beneath the graft. These dead spaces rapidly become filled with blood, which insinuates itself more and more under the skin and so prevents a successful "take." For the same reason, it is good practice to puncture the grafts with a very fine needle to allow any exudate to find its way to the exterior rather than be pent up between the skin and its bed.

When the operation is complete the cavity can be seen covered with the grafts, still with their tulle gras backing in place. These small pieces of gauze are left till the first dressing on the fifth day, when they can be painlessly picked out without loosening the grafts. No other packing is left in the cavity. The dressing of the radical mastoidectomy wound is thus rendered relatively painless. The subsequent dressings are done daily and consist in picking out desquamated outer layers of the skin grafts and removing secretions.

The placing of grafts on an infected bed is always some thing of a gamble. The surgeon's judgment of the virulence of the infection will dictate whether he will graft at the time of the original operation or defer it until bacteriological examination of the wound suggests that the chances of a "take" are greater. Young states that in grafting an infected area, fibrin fixation alone, without pressure dressings, gives less satisfactory results than when pressure dressings are employed. He states that this applies more particularly to large thick grafts, and that small thin grafts have about the average expectancy of survival.

In this manner 47 mastoidectomy cavities have been grafted. Of these, 30 were classical and 17 modified radical mastoidectomies. Primary grafting was carried out in 38, delayed in 9. The graft failed entirely to take in 4 cases, in 29 there was apparently complete survival of the graft, and in the remaining 14 over 75% of the graft survived.

Summary

Thrombin has proved of little value in arresting haemorrhage from the tonsillar fossae and in epistaxis.

Used in nasal and mastoid surgery, it permits dispensing with gauze packing, particularly after submucous resection of the nasal septum, and retaining skin grafts in the radical mastoidectomy cavity.

TAPHYLOCOCCAL SPINAL OSTEOMYELITIS WITH ACUTE EXTRADURAL ABSCESS

BY

GUY BLACKBURN, M.B.E., F.R.C.S.

Lieut.-Col., R.A.M.C.; Officer in Charge, Surgical Division

AND

R. P. JEPSON, M.B., Ch.B.

Captain, R.A.M.C.

An analysis by Dandy in 1926 showed that 25 cases of spinal osteomyelitis with extradural abscess had been reported up to that time. Only two of the patients recovered, and except in the case there was "no evidence to indicate that the nature of the lesion was more than roughly guessed" (Taylor and Kennedy, 1923). The concluding words are also of interest: "Whether an epidural abscess may eventually be diagnosed before implication of the spinal cord and before the appearance of a spinal block remains to be seen."

Numerous authors since that date have recorded cases successfully diagnosed and surgically treated (Abrahamson, McConnell, and Wilson, 1934; Stammers, 1938; Browder and Meyers, 1941).

As late as 1944, however, when the clinical syndrome had not been accurately defined in the literature, Boger states: "From the literature, as we have reviewed it, there are 84 reported cases with a mortality of 35%." All authors agree that in non-operated cases the disease is invariably fatal. The mortality, then, can reasonably be associated with delay in making the diagnosis—a state of affairs less likely to obtain when the clinical syndrome of fever, spinal muscle spasm, and pain in the back of rapid onset and in a site where alternative possibilities are rare gains more general recognition. The incident osteomyelitis of the spine and incipient neurological signs are indications for surgery without delay.

The surgical technique, when reported, has been that common for all abscesses—namely, incision (by an extensive laminectomy) within the limits of the extradural abscess) and drainage, either by repeated packing or by a large-bore drainage-tube (Stammers, 1938; Mixer and Smithwick, 1932). The natural outcome of this has been a lengthy and difficult period of hospital treatment while the spinal cavity collapsed or a sinus closed. Early diagnosis, however, should allow primary closure in a high proportion of cases, as the original focus of infection is frequently laminar and therefore easy of access. The organism, moreover, is most commonly a penicillin-sensitive staphylococcus.

The advantages of immediate closure of a spinal wound are, in fact, so striking, alike to patient and to nursing staff, that we have been prompted to record this single successful case.

Case Report

L/Cpl. J., aged 36, was admitted to the medical division of a military hospital on Jan. 19, 1946, with the provisional diagnosis of lumbago. He was complaining of general malaise and a constant severe dull ache in the left lumbar region. This had begun eight days previously, and was aggravated by any movement of the spine—so much so that he was unable to turn over in bed without extreme discomfort. The pain was not worse on coughing or sneezing, but latterly had radiated down the back of both legs. There was no relevant previous history or any recent minor sepsis. Micturition was normal; temperature 100° F. (37.8° C.), pulse rate 70. The left lumbar musculature was in spasm with a marked scoliosis to the right. There was decided tenderness to deep pressure over the erector spinae at the level of L 3-4 and below and medial to the renal angle. Flexion of the neck caused an increase in lumbar pain, but there were no abnormal neurological or genito-urinary findings. White cells, 8,000 per c.mm., polymorphs 90%, lymphocytes %, monocytes 3% (repeated twice). Erythrocyte sedimentation rate, 9 mm. per hour (normal 8).

Jan. 20.—Temperature, pulse, and respiration normal. The left aralaminar musculature opposite L 3-4 was more acutely tender than on the previous day and showed slight swelling and increase in local heat. There was no tenderness over the spinous processes. A diminution was noted in the left ankle-jerk.

Jan. 21.—An exploration by needling showed thick creamy pus in the paravertebral groove deep to the area of tenderness. Skiagrams failed to demonstrate any bony lesion in the lumbo-sacral vertebrae and there was no distortion of the psoas shadow. As the left ankle-jerk was still noticeably weaker than the right a diagnosis was made of osteomyelitis of the lumbar spine with extradural abscess.

Jan. 22.—The bacteriological report showed that *Staphylococcus aureus* had been isolated in the pus. No tubercle bacilli were seen in Ziehl-Neelsen films. Operation was therefore undertaken without delay. A midline incision was made from L 2 to S 1. Thick creamy pus was found in considerable quantity deep to both erector spinae muscles. The laminae of L 3, 4, and 5 were soft and necrotic and were removed, releasing an extradural abscess of thick pus, extending up to L 2 and down to S 1. It had not separated the close dural attachment to the posterior common ligament except inferiorly. The dura over an equivalent area was covered by fleshy greyish-red granulations. It was everywhere intact and pulsated freely. The wound was completely closed by layered catgut sutures and a small penicillin tube was brought to the lower end of the extradural abscess by a separate stab incision.

2,500 units of penicillin in 5 ml. were instilled twice daily down the tube for five days, and 15,000 units were administered parenterally three-hourly for 14 days.

Immediately after operation the patient became free from the severe aching lumbar pain and was able to move freely about the bed. His temperature showed a nightly rise of 1° for the first week, but after that it settled. The lumbar wound and the penicillin stab incision healed by first intention, and he started vigorous physiotherapy at 10 days. He was walking at the end of the first fortnight and his ankle-jerk had returned to normal. At the end of two months his white cells numbered 8,000 per c.mm. The sedimentation rate was 8 mm. per hour, and, beyond the deficiency due to the laminectomy, there was no evidence of bone disease. He was symptom-free and ready to return to duty.

Medical Memoranda

Intussusception after Emergency Colostomy

The following case is placed on record because of the uncommon type of intussusception.

CASE REPORT

We were called to see a man aged 74 on the night of Sept. 27, 1945. He complained of abdominal distension and constipation for 10 days. A soapuds enema was given with excellent result. This was repeated the next morning, but neither faeces nor flatus was passed. He was admitted to St. Vincent's Nursing Home under Mr. Hamilton Bailey for complete intestinal obstruction.

On admission his clinical condition was very poor. The pulse was barely perceptible, his face was pale and his extremities, especially the feet, were deeply cyanosed. Gastric aspiration produced a small quantity of bile-stained fluid. In the operating theatre continuous intravenous glucose-saline was administered. After he had received one pint (568 ml.), together with a hypodermic injection of methedrine, his pulse and colour became a little better, but, whereas previously he had lain in a quiet semi-comatose condition, he now became noisy and restless, especially when some local analgesic was introduced into the skin of the abdominal wall. Infiltration was continued with the objective of transverse colostomy, but it was impossible to quiet the patient sufficiently for the operation to proceed under local analgesia alone. Pentothal was injected into the saline delivery tube, less than 0.05 g. being given. He fell asleep. A loop of colon was delivered through the incision; it was of the dimensions of the inner tube of a motor tyre. In passing it was noted that the loop was not of a transverse colon as would be expected from the position of the incision; the mesocolon was not attached to it. The apex of the loop was opened and a rubber tube was sewn in. Much gas but no faecal matter escaped. After completing the colostomy the patient was returned to bed with little hope of his recovery. For three days he remained in a more or less moribund state, and, although the distension had assumed less extravagant proportions, he was still distended and the colostomy had not acted. On the evening of the third day, after diligent irrigation through the colostomy, the patience of the sister in charge was rewarded by a copious motion. From that time his condition steadily improved, and at the end of three weeks he was convalescent. A barium enema revealed ballooning of the pelvic

colon, and barium issued from the colostomy opening. No sign of an obstructive growth of the colon was seen, and a tentative diagnosis of volvulus was made. Uncertainty as to the exact nature of the obstruction, his advanced years, and his erstwhile moribund condition were the factors that led to a decision to send him home with a colostomy belt and with the proviso that if all went well his case was to come up for review in three months' time.

Three weeks after this there was a prolapse of about 2 in. (5 cm.) of gut through his colostomy opening, which we successfully reduced. On Jan. 13, 1946, we were hastily summoned and found more than a foot (30 cm.) of gut prolapsed through the colostomy opening. The appearance was that of a dark sausage-like mass issuing from the colostomy. We endeavoured on two occasions in the next few hours to reduce the intussusception without success. The patient was in good condition, without pain or even discomfort. Mr. Hamilton Bailey came down and wrapped the intussusception in a towel and squeezed it for some moments in order to reduce the oedema. This appeared moderately successful. He then proceeded to attempt to reduce the apex in accordance with the orthodox method of reducing a paraphimosis. This also was partially successful, but about 4 in. (10 cm.) still remained without. Up to this time the patient had had but little pain. An effort was made with greater force, and the surgeon's thumb passed right through the mucous membrane and entered the peritoneal cavity, some clear peritoneal fluid escaping. Shortly after this some of the intussusception which had been reduced was extruded. The patient was sent to hospital. Under general anaesthesia Mr. Bailey freed the colostomy opening (with the intussusception protruding therefrom) from the abdominal wall and delivered 18 in. (45 cm.) of distal redundant colon and about 8 in. (20 cm.) of proximal colon. The intussusception had begun in the colon proximal to the colostomy opening. Before proceeding further it was ascertained by intra-abdominal palpation that there was no growth or other abnormality to account for the original obstruction. The two limbs of the colon were anastomosed by the Paul-Mikulicz procedure, and the intussusception, together with the redundant portion of the colon, was excised. The total length of colon removed, which included the intussuscepted portion, was nearly 3 ft. (90 cm.). The patient made a good recovery.

COMMENTARY

Intussusception is usually seen only when the abdomen is opened by the surgeon on the operating table, but the exceptions are the rare types that extrude through a colostomy or similar artificial opening, and those rare ones seen passing out through the anus. Very few cases of the former type have been recorded—one, by Milligan (1926) of an intussusception through an enterostomy and one by Turner (1936) in an article on the various complications of colostomies. The latter case was the only one in 175 cases of various complications of colostomies. Both these cases were treated in the same way as the one described above.

We are indebted to Mr. Hamilton Bailey for his co-operation and kind help in the preparation of this report.

Plant Dermatitis in the Bahamas

A shrub *Metopium toxiferum*—"poison wood" or "poison ark"—flourishing throughout the open spaces of the Bahama Islands and in southernmost Florida (where it is also known as "doctor's gum"), has attracted little attention outside the immediate vicinity. Yet it contains a toxin at least as powerful as that of the well-known North American "poison ivy" (*Rhus toxicodendron*), thereby entitling this colonial product to at least a short note.

Botanical Note.—The plant *M. toxiferum*, of the family Spondiaceae (Small, *Florida Trees*, p. 60), varies in size from a small shrub to a tree 40 ft. (12.2 m.) high (Britton, *Bahamas Flora*, p. 244). The bark is thin and brown, with a moist, green, shining layer beneath, which becomes orange with increasing age. Its branches are widely spreading, and the leaves, up to a foot (30.48 cm.) long, alternate, with three to seven ovate, pinnate, glabrous leaflets, bright green and shining on top and dull on the under surface. The efflorescence is a many-flowered compound raceme with short pedicel. Florets have five short ovate sepals, five white separate petals, and five separate stamens with large anthers. The fruit is a green drupe, becoming yellowish when ripe.

The Toxin.—This is contained in the "milk" beneath the bark, in the leaves, and in the fruit. On the bark and leaves it frequently oozes up to the surface, where it or some other product associated with it in the juice becomes oxidized and produces black stains. It is a type of gum resin, very similar to that of poison ivy.

CLINICAL NOTE

Many R.A.F. personnel engaged on clearing undergrowth around the station were affected. Among the white residents there is regularly at the New Year a crop of cases of poison-wood dermatitis, following the incautious gathering of Christmas trees.

After contact with the toxin there are usually no symptoms for a few days, when small papules, rapidly becoming vesicular appear at the site of contact, with considerable itching and variable surrounding erythema. Superficial ulceration of these vesicles occurs, and the rash spreads both locally and to distant parts of the body. Crops of small, deep-set papulo-vesicles appear on face, trunk, and legs. Local weeping and crusting eczematization may occur, and the whole process continues for weeks after the initial contact. Sometimes the reaction is more urticarial, with gross erythema and oedema affecting and directly spreading from the contact area. In less sensitive people retrogression of the rash may occur at any stage. In one patient blisters up to an inch (2.5 cm.) in diameter formed over hands, forearms, body, face, and legs, breaking down to superficial ulcers, some of which became secondarily infected. The appearance resembled a papulo-necrotic tuberculide. He was febrile on admission, and remained in hospital 20 days.

SENSITIVITY TO THE TOXIN

One drop of juice from the underbark of a plant 5 ft. (1.52 m.) high was placed on the forearm of each of twenty volunteers. One developed a generalized spreading rash lasting several weeks, one a severe local erythematous reaction, 12 local population of varying degree, and 6 were unaffected. On my own arm itching occurred a few minutes after application, followed by the characteristic black staining and the development of a small papule by the next day. The local area became eroded after four days, with superficial ulceration and surrounding vesiculation. Resolution started on the seventh day. One drop of berry juice, however, caused a widespread erythematous vesicular eruption lasting some weeks. (This was not due to acquired hypersensitivity, since subsequent drops from the bark actually produced less reaction than the first.)

The phenomenon of generalized spread to non-contact areas seemed to indicate the production of a general allergic cutaneous tissue reaction of systemic dissemination. However, the possibility existed that the original toxin or product of it lurking in the blister fluid at the contact site was carried over the body by the patient's finger, producing multiple local reactions. Blister fluid from one patient with the disseminated rash was therefore tested on other parts of his own skin and on the skin of other sensitive subjects, with and without previous excoriation of the skin by a needle. In no case was any lesion produced, so that the hypothesis of contact spread would seem to be disproved.

W. P. U. JACKSON, M.B., M.R.C.P.,

Fl.-Lieut., R.A.F.V.R.; formerly Medical Specialist in the Bahamas.

Traumatic Axillary Venospasm

This condition has been described by various people, especially Matas, and was first recognized about 60 years ago. It occurred most commonly on the right side, and various theories have been advanced to account for it. Sudden abduction of the arm may cause trauma to the axillary vein by contact with the subclavius muscle; this may either give rise to a generalized venospasm or actually damage the intima of the vein, with venospasm and thrombosis, hence the name "traumatic axillary vein thrombosis." Matas says that there is a polyvalent causation, in indirect trauma to the vein and its immediate environment, including lymphatics and perivenous sympathetic plexus, and that thrombosis is not essential.

The case described below is one of traumatic axillary venospasm without thrombosis, and in this instance the opportunity of observing the veins and brachial artery was taken. The brachial artery was very sensitive and the slightest handling was sufficient to put it into spasm, so apparently there must be a generalized increased sensitivity of the neurovascular make-up of this particular patient to account for the condition. The treatment adopted—cervical sympathetic block—does not claim to be original, but I have not seen any reference to it. The cervical sympathetic block has a twofold effect—viz., it relieves the venospasm, and also the arteriospasm, which in time will increase the venous return.

CASE REPORT

The patient was a female aged 35, married, but with no children, and was admitted complaining of swelling of the left arm, which was tense but not very painful. She said that four hours ago, when putting her left arm into her overcoat sleeve, she felt something

atch in her axilla, and that almost immediately her whole arm began to swell and felt useless, tight, and tense. There was no previous history of a similar condition.

On examination her general condition was seen to be good. Her temperature was 98° F. (36.7° C.), and her pulse rate 70. The left arm was diffusely swollen, tense, and blue from the middle of the deltoid muscle to the finger tips. The superficial veins on the dorsum of the hand were congested, and failed to empty on elevating the arm above the head. The upper chest veins were congested, but emptied on compression. The axillary vein was not palpable. The radial pulse was diminished in volume in comparison with the opposite side. There was no increase in heat of the limb. A small aceration was visible over the lower part of the cubital fossa, which had occurred about ten hours previously.

Operation.—A general anaesthetic was given, and it was decided to explore the laceration in the lower part of the cubital fossa to see the state of the vena comitans of the brachial artery. All the veins encountered were in a state of spasm and failed to bleed on cutting. The brachial artery was seen and appeared normal. It was retracted very gently and immediately went into spasm, showing the excessive sensitivity of the neurovascular system. The radial pulse at this stage disappeared, so it was decided to close the wound. The patient was then turned on her right side and a cervical sympathetic block was performed. The stellate ganglion and the second and third left thoracic ganglia were injected with 10 ml. of 2% procaine each by the posterior approach. On turning the patient on her back it was noticed that the hand was now becoming pink and that the radial pulse, which had disappeared after the brachial artery spasm, was now returning.

One hour later the radial pulse had fully returned; the hand was now pink and the superficial veins were empty. Twelve hours later the swelling of the hand and forearm had disappeared and the colour was normal. The upper arm, however, was still discoloured pink rather than the previous blue, and still swollen, but not so much as it had been. Twenty-four hours after the sympathetic block the whole arm was back to normal, and after that the patient made an uninterrupted recovery. X-ray examination failed to demonstrate any sign of cervical ribs.

HUGH MACCARTHY, M.R.C.P.I., F.R.C.S.I.&Ed.,
Resident Surgical Officer.

Royal Victoria Infirmary,
Newcastle-upon-Tyne.

A Case of Secondary Syphilitic Iridocyclitis

Duke-Elder states that a severe and acute iridocyclitis is not uncommon in the early secondary stage of syphilis; thus, among 10,000 syphilitics studied by Moore (1931) at the Johns Hopkins Hospital, the expectancy of its development with the generalized secondary outbreak was 4.5%. I have not seen any comparable R.A.M.C. figures, but have the impression from R.A.M.C. venereologists that the complication is much rarer than this, and therefore the occurrence of a case is interesting enough to report. It is the first one I have personally seen in 3½ years in the Army.

CASE HISTORY

B. W. reported on Feb. 21, 1946, that both eyes had been inflamed for two weeks. He was found to have a mild bilateral iridocyclitis with fine keratitis punctata in each eye, a roseola of fine blood vessels on each iris, and posterior synechiae in the left eye only. He had a history of venereal infection two months ago, and gonorrhoea two years ago. General examination revealed secondary syphilis: the prepuce had an irregular margin and multiple ulceration round the edge; there were moist papules at the peno-scrotal junction; condylomata were present in each groin, with inguinal adenitis; no generalized rash was seen; the tonsils and pharynx were both congested. The Kahn test was positive.

Sodium penicillin 10,000 units 3-hourly for one day gave no Jarisch-Herxheimer reaction, so the dosage was increased to 40,000 units 3-hourly for 7½ days. With the penicillin were given daily mephariside injections to a total of 0.56 gr. (36.4 mg.) in 15 days. Atropine ointment and heat were used for the eyes. In one week they were much improved, with disappearance of the roseola, and in two weeks the ocular condition had entirely subsided, the only sequelae being a few pigmented dots of keratitis punctata, one posterior synechia, and a little pigment on the anterior line capsule in the left eye.

I wish to express my thanks to Major R. S. Garden, R.A.M.C., A.O.C. 48 British General Hospital, for permission to publish this paper.

48 General Hospital.

REFERENCE

Moore, J. E. 1931. *Amer. J. Ophthalm.*, 14, 110.

The Manchester Ear Hospital has been at work for ninety years, and now receives patients from areas as far distant as Derbyshire, Wales, and London. Owing to staffing difficulties and redecoration of the wards fewer patients were admitted last year than in the previous one (744 against 849); but on the other hand 6,816 new out-patients were treated—an increase of 72.

Reviews

RARE DISEASES

Rare Diseases and Some Debatable Subjects. By F. Parkes Weber, M.D., F.R.C.P. (Pp. 174; illustrated. 15s.) London: Staples Press Ltd.

As Dr. Parkes Weber truly remarks, it has been repeatedly suggested to him during the last thirty years that he should write a book on rare diseases. It is, therefore, somewhat disappointing to find signs of hasty compilation. This detracts from the pleasure of reading but not from the value of the book. He recognizes that the importance of a rare disease lies not merely in its rarity but in the light it throws on less extreme departures from the normal and sometimes even on the normal itself. He shows how some of the rare syndromes may involve a large number of systems in the body, but minor versions of such syndromes occur, so that there is a continuous series from the complete form to *formes frustes*.

In the earlier part of the book a useful classification is observed according to which tissues are mainly involved. The real gist of his argument is explained best in Chapter 16, entitled "Inborn and familial tendency to the development of hepatic cirrhosis." This enables him to develop his views of the inborn tendency of an organ inferiority as the basis of most of the diseases he is considering. He speaks of these as the congenital-developmental class under the convenient inclusive term "dysbiotrophy." Here his comments on Kinnier Wilson's description of progressive lenticular degeneration combined with cirrhosis of the liver are of special interest. Familial incidence in this rare disease has been emphasized by Wilson himself as well as by later authors. The association between these two conditions seems curiously remote and yet there are other instances of this connexion. Some of these hepatic conditions may work in either direction; thus the telangiectases of the Osler type may occur in families and involve haemorrhage from the stomach without the presence of any skin lesions. In some of these cases hepatic cirrhosis has been found—presumably due to a congenital dysplasia of the small blood vessels, including those of the liver. Conversely, in advanced hepatic cirrhosis, spider-like telangiectases are common on the face and hands. Here they follow and do not anticipate the cirrhosis.

It will be seen that the book even in its present form is a mine of interesting information which may well cause us to think. Apart from our initial criticism we can cordially congratulate the learned author on putting on record so much that is helpful.

A PHILOSOPHY OF SEX

Sex, Life, and Faith. A Modern Philosophy of Sex. By Rom Landau. (Pp. 319; illustrated. 21s.) London: Faber and Faber.

The author is not a doctor or a priest, but certainly has a large experience and knowledge of life. From this he has learnt the basic material of how man and woman have approached the problems of sex and behaved in this respect throughout the ages in all sorts of communities and under all sorts of conditions of society. What makes the wealth of material expounded in this book so valuable is that the author has throughout been able to expound it without prejudice and with a sympathetic understanding of why any particular behaviour has manifested itself. Whether he is dealing with polygamy, polyandry, homosexuality, or any other manifestation of the sexual urges of men and women, he is equally open-minded and objective. Though maintaining that the monogamous union is the ideal he realizes that this cannot be reached unless the union itself is ideal in that it really satisfies the aspirations of both partners. There must be no repression, false shame, or reservation on either side, and he recognizes that without this the ideal of sexual behaviour is to all intents and purposes unattainable. Nevertheless, such an ideal is in the author's view attainable in certain conditions. First, it is necessary to sweep away all prejudices and false values such as are maintained by the puritans, the respectable, and the smugly complacent people who make up such a large proportion of our moralists and ecclesiastical experts. Secondly, it is necessary to recognize fully the importance, strength, and essential place in life of the sexual instinct and

allow for its full gratification for both men and women by modifying our social education and probably many of our laws and customs. Thirdly, and most important of all, the religious "instinct"—the author is convinced that this is innate and fundamental in everyone—must be developed and strengthened into a firm belief in God.

The author pours scorn on the emotional revivalist schools and the puerilities of certain fashionable groups, but believes that by genuine private effort a real conversion may be attained which will result in a true control of the sexual instincts so that a solution to the conflict between sex and "morals" may be found. How many people will be able and willing to make the effort to achieve this victory is open to question, but whoever is interested in the social life of our times—and surely doctors above everyone must be or ought to be—should read this sincere, erudite, and clearly written book.

DERMATOLOGY AND SYPHILOLOGY

The 1945 Year Book of Dermatology and Syphilology. Edited by Marion B. Sulzberger, M.D. Assistant Editor, Rudolf L. Baer, M.D. (Pp. 559; illustrated. \$3.00 or 18s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

This now well-known annual keeps up its reputation and we admire the industry of the editors in collecting and presenting such a mass of contemporary literature in brief form. Notwithstanding their statement that great advances have been made in dermatology during 1945, we do not recall any specially noteworthy advance, though there is evidence of great activity in every department. Perhaps, however, 1945 will stand out in the history of dermatology as the year in which the treatment of lupus vulgaris by calciferol was first instituted, and that method, initially tried by Dowling at St. Thomas's, London, appears to have been published too late for mention in the year book before us.

The special article with which the editors always begin is this year devoted to skin tests in drug eruptions and also their management. There is an important addendum on the lichenoid dermatosis due to atabrine (usually spelt atebirin on this side of the Atlantic) with which the anti-malarial measures pursued so vigorously in the Eastern theatres of war have made us painfully familiar. In venereal disease much space is rightly given to the discussion of the place of penicillin in the treatment of syphilis. There seems to be a consensus of opinion that the best results are obtained by a combination of penicillin with the arsenical antisyphilitic drugs, and bismuth is not yet superseded. It is sad to think that the progress made between the two world wars in reducing the ravages of syphilis has been very largely lost during the second, nor are the conditions prevailing during the long-drawn-out armistice, especially in Europe, such as to help in regaining the lost ground. In the American Forces in Europe venereal disease has become the No. 1 medical problem. The editors think it probable that the post-war civilian population will continue to present venereal disease problems as great as those which followed the last war. Mitigation of this gloomy outlook it may at least be said that owing to penicillin and the sulpha drugs the period of effective treatment has been greatly shortened.

A cheerful feature of this year's book, as of recent numbers, is the "Quiz Section" on the dust jacket. It really deserves incorporation within the bound volume. Those who fancy that they are well abreast of dermatological literature should test themselves on the twenty questions posed. We doubt if there are many, even in the ranks of dermatological specialists, who would get a 50% marking at this examination. Deficiencies can be made good by study of the text.

ADULT PSYCHIATRY

Essentials of Neuro-Psychiatry. A Textbook of Nervous and Mental Disorders. By David M. Olkon, M.D. (Pp. 310; illustrated. 22s. 6d.) London: Henry Kimpton.

In this new survey of psychiatry the author sets out to present a conception of body-mind unity, but as so often happens there is more stress on the contribution of the body than of the mind. As in so many textbooks of psychiatry the section on psychoneuroses is weak, with too much relative attention to hysteria at the expense of the much more fundamental anxiety state. Though not specifically stated, the book is obviously directed to those who are dealing with or will have to deal with war

psychiatry, yet there is no recognition that in World War II the dramatic presentations of hysteria are much less important than the fear neuroses. In a comment on a case history of a hysterical girl the author remarks "the interesting feature is that there is such an entity as conversion hysteria." This sort of bias is evident throughout, and there is no real appreciation of modern medical psychological methods and their success in treatment.

The discussion of the psychoses is better but is rather unequal; the subject in which the author is himself particularly interested being given more prominence than is usual in what purports to be a comprehensive textbook. Thus there is an interesting discussion on the role of the capillary dysfunction in schizophrenia, and the reader is left wishing that all other aspects of this and other conditions were equally well dealt with. Again, in the section on sexual perversions sadism is dismissed in a small paragraph while transvestism is discussed at length, but perhaps without great enlightenment, because the author had one or two cases under his own observation. In order to keep the book within small compass there is a great deal of compression, and while most subjects relating to psychiatry will be found mentioned consecutive reading is not easy. The subject-matter deals almost exclusively with adult psychiatry, and although cases of adolescent abnormality are quoted there is no appreciation of modern child psychiatry.

Useful hints of relevant literature are given at the end of each chapter and the book is well illustrated by case histories and excellent photographs and diagrams.

Notes on Books

At Lambaréné in Wartime is the title of British Bulletin No. 11 (Spring, 1946) of Dr. Schweitzer's Fund. This pamphlet, written by the gifted musician himself, covers the history of his hospital in French Equatorial Africa from 1939 to 1945. The hospital escaped direct damage from the war, for both sides agreed not to bomb it during the short struggle between the de Gaulle and Vichy forces in the colony. But indirectly the war so increased the normal difficulties of administration that the work of the hospital had to be heavily curtailed, and, but for remarkable foresight shown in the buying of provisions and in other matters, it would have had to be closed altogether, to the great detriment of the wide area which it serves. The booklet may be obtained (price 1s.) from Mr. T. D. Williams, Treasurer, British Council for Dr. Schweitzer's Hospital, 5, Castleton Mansions, London, S.W.3, to whom all subscriptions or donations may be sent.

The fifth series of *Exposés Annuels de Biochimie Médicale* has been prepared under the direction of Prof. MICHEL POLONOVSKI of the Paris Faculty of Medicine. It is published by Masson et Cie 120, Boulevard Saint Germain, at 500 francs. The ten contributions by twelve authors deal with various important aspects of medical biochemistry. Most of the longer papers have bibliographies, though for reasons that all can understand the references to Anglo-American work do not cover publications since 1942. These valuable reviews began in 1938; the second of the series was published in 1939, the third in 1942, the fourth in 1944, and the present volume is dated 1945.

Dr. A. P. CAWADIAS's study of hermaphroditism, which was originally given as the Vicary Lecture at the Royal College of Surgeons in 1940, evidently attracted a good deal of attention, for a second edition of the book, *Hermaphroditos: The Human Intersex* (William Heinemann Medical Books; 15s.), based on that lecture has been called for. In this edition the chapter on the physiopathology of intersexuality has been rewritten in order to make clearer the two great classes, constitutional and endocrine, involved. The clinical chapters have also been rewritten, so as to make clearer these forms as they manifest themselves. Much learning and thought have been devoted to this work.

PROF. FRANCIS J. BROWN's *Antenatal and Postnatal Care*, first published eleven years ago, has now reached a sixth edition (J. and A. Churchill: 25s.). The continuing popularity of this book must be a source of much gratification to its author, who has carried on and amplified in London the pioneer work of John William Ballantyne in Edinburgh. He has revised the text throughout and made some changes and additions. Amendment was chiefly necessary in the chapter on erythroblastosis and the Rh factor (which was a new feature of the fifth edition), and in the chapters on placenta praevia on the toxæmias of late pregnancy, and on venereal diseases in pregnancy. The chapter on the uses and value of radiology in obstetrics has again been revised by Prof. Chassar Moir.

SATURDAY AUGUST 31 1946

ASSESSMENT OF DISABILITY IN DUST
DISEASES OF THE LUNG

Undergrass and Leopold¹ have recently suggested that the form of dust inhalation that occurs in electric arc welders and workers exposed to similar dusts should be called "benign pneumoconiosis" in order to contrast it with diseases resulting from the inhalation of siliceous matter. The latter produces a fibrous reaction, and even if tuberculosis is not a complicating condition the lung is still gradually destroyed. At the same time it is necessary to stress that the lung cannot become a physiological dust trap and yet retain its normal structure and function. It would seem possible that heroic quantities of any dust, no matter how innocuous they might be in small concentrations, would in time overwhelm the defences of the lung and accumulate in such amount as to impair function. Such a form of lung disease would obviously be due to mechanical causes—the physical presence of large amounts of inert foreign material.

Since pneumoconiosis is an industrial disease the question of compensation under the Workmen's Compensation Act always arises. Compensation is paid for disability acquired by the workman through the inhalation of dust while at work; it has, however, always been recognized that the diagnosis of the disease and the assessment of disability are difficult. For this reason the highly complicated silicosis Acts were passed by Parliament and the Silicosis and Asbestosis Board was created. But difficulty of the assessment of disability is still there, and at present it is decided largely by radiographical appearances. This method is not satisfactory because it is impossible to differentiate between the nodulation caused by iron oxide in the siderosis of arc welders and that shown by the fibrous nodules of silicosis. Similarly, the reticulation in lungs of arc welders, South Wales coal-miners, and the workers in iron foundries are essentially similar; yet the men with iron oxide in their lungs suffer little or no disability, as was first suggested by Doig and McLaughlin² and recently demonstrated with full physiological tests by Enzer, Simonson, and Evans.³ After their survey of chronic pulmonary disease in South Wales coal-miners Hart and Aslett⁴ suggested that the inclusion of reticulation as a compensatable disease would not lead to any large increase in the certification rate, because only a small proportion of these cases were significantly disabled; but, in fact, the enactment of the Pneumoconiosis in Coal Miners Bill, 1943, has been followed by a very large increase in the number of certifications. This is due to the difficulty of assessing disability, and there is no doubt that many men with reticulation who are not disabled are obtaining disablement certificates. It would seem, there-

fore, that compensation should not be awarded until disability actually occurs, which may be quite a long time after characteristic x-ray changes are detectable. If these are discovered and there is no disability the man should be removed from the silicosis risk and trained to fill a job which will give him equal or better prospects in life.

It is therefore essential to look for some other than the x-ray method of assessing disability—a method that must also be simple and practical and can be used by those undertaking surveys in factory and mine and by the Silicosis Board, besides those engaged on work in the laboratory and on long-term projects. Attempts have been made to arrive at some measurement by comparing the areas of the lung fields on radiographs in expiration and inspiration. In the clinical examination of pneumoconiotics the two most valuable observations are the marked diminution of air entry on auscultation and the poor chest measurements on inspiration and expiration, and it is hardly likely that more information than this can be obtained from x-ray examination. However, McCann and Kaltreider⁵ have suggested that if the ratio of the areas of the lung fields measured with a planimeter on x-ray films of the chest doubly exposed at maximum inspiration and maximum expiration exceeds 71% there will certainly be disability. Other possible methods of gauging disability include reactions to standard exercise, measurements of oxygen content of blood, blood sedimentation rates, and estimation of lung volume, including vital capacity and residual air. The fact that no two workers employ exactly the same exercise-tolerance test is itself evidence of the unsatisfactory nature of these tests, and it is doubtful if complicated exercises involving the use of dumb-bells or pedalling bicycles give much more information than simple stepping up and down on a box. In any event little information is likely to be gained unless the disease is advanced and the disability obvious. Measurement of the oxygen content of the arterial blood is complicated by the fact that the technique of arterial puncture is difficult and the range of complete and incomplete saturation of the blood with oxygen is narrow. Nevertheless, this is a promising field of research, and if it is possible to develop an oximeter which can estimate the oxygen saturation of the blood from the lobe of the ear the solution of the problem might be in sight. Little work has been done on blood sedimentation rates, and nothing is known of normal levels throughout the day in the industrial population as a whole. Most patients, however, who have real disability from pneumoconiosis have an increased sedimentation rate: this may in part be due to infection either tuberculous or non-tuberculous, but it is quite possible that the onset of the disability is closely related to the onset of infection. It is therefore possible that the blood sedimentation rate will prove to be a valuable simple test.

Vital capacity is at present the best guide, and if tracings are taken in the way suggested by Christie⁶ a permanent record is obtained. Vital capacity tracings are of no use for comparing one individual with another, but a series of tracings which show a decreasing vital capacity in a given individual over a period of time is of high significance.

¹ *J. Amer. med. Ass.*, 1945, 127, 731.

² *Lancet*, 1936, 1, 771.

³ *J. industr. Hyg.*, 1945, 27, 147.

⁴ *Med. Res. Counc. Sp. Rep. Ser. No. 243*, 1942, 191.

⁵ *Proc. Med. J.*, 1937, 42, 901.

⁶ *J. clin. Invest.*, 1934, 13, 295.

By taking the weight and height or sitting height of the individual it is also possible to compare his actual vital capacity with the expected one for one of his surface area. The greatest difficulty of these tracings rests with the ability of the patient to co-operate; some persons develop a sense of suffocation and are quite unable to perform the test, and when men seeking compensation are under review the operator can never be certain that they have emptied or filled their lungs to the limit. This can to some extent be checked by measurement of the residual air, and McMichael's⁷ modification of Christie's method is comparatively simple, as is that described by Cornand.⁸ McCann and Kaltreider⁵ have shown that a decrease in the total capacity and the vital capacity of the lungs, with an increase in residual air, is usual in advanced pneumoconiosis, and they consider that when the ratio of $\frac{\text{residual air}}{\text{total capacity}}$ exceeds 40% some degree of functional impairment is usually apparent. These authors also attempted to combine this method of investigation with a response to exercise, and thought that a better method of estimating disability was that of measuring the total ventilation during five minutes of exercise at the rate of 300 kilogramme/metres per minute and three minutes of subsequent rest. The resulting ratio $\frac{\text{total ventilation}}{\text{vital capacity}}$ is of great functional significance.

They found that in normal healthy men the ratio varied from 20 to 48, and that when the value rose above 55 shortness of breath was experienced. Estimations of the pulmonary reserve at definite rates of work also give an index of functional ability. Normal men have a pulmonary reserve of 55 to 73% when working at 300 kilogramme/metres per minute when they are using 27 to 45% of their maximal ventilating capacity, and dyspnoea is experienced when 50 to 60% of the maximal ventilating capacity is used.

The present situation may then be summarized by saying that there is no satisfactory simple method of assessing disability. Consideration must be given to physical examination, chest measurements, blood sedimentation, and vital capacity; the presence of x-ray shadows in the form of opaculation, or even nodulation, does not of necessity mean the patient is disabled. C. M. Fletcher, who is director of the Medical Research Council's Pneumoconiosis Unit in South Wales, is fully aware of all the difficulties and knows that until this problem is solved no great advance in the study of silicosis is possible. He is therefore devoting much time and man-power to research on the problem, and it is to be hoped that his efforts will soon be rewarded and some simple method of assessing disability developed.

MALARIA AND ITS CONTROL IN MALAYA

Control of malaria, from being a somewhat experimental and one might almost say often a rather debatable performance, has within a relatively few years become, partly as a result of increased knowledge and experience in carrying out measures against the disease and partly due to development of more effective insecticides and methods

of using these, a highly practicable proposition in which if essential requirements are recognized, success may be assured. In a pamphlet entitled "Notes on Malaria and its Control for Planters and Miners," issued from the London School of Hygiene and Tropical Medicine, incorporating the Ross Institute of Tropical Hygiene, Dr. Macdonald, director of the institute, has explained and illustrated in simple language the problem of malaria and its control. The pamphlet is published under the authority of the Ross Institute Industrial Advisory Committee, the Malayan Chamber of Commerce and the Rubber Growers Association and has been especially written relating to conditions in Malaya, though expanded to give some information applicable to most areas where there is industrial development in the Tropics.

An interesting feature of this up-to-date account of the position of methods of malaria control is that it is written for the instruction and guidance of the layman and yet something more than a merely popular account. What exactly is the position of the layman? He is clearly a deeply interested party in the matter, for it is he who will spend the money in carrying out such measures if he decides to do so and he to whom the benefits (if any) will come in terms of lowered costs or greater profits from such enterprises as he may be concerned with. It does not follow that he himself requires the knowledge and experience to carry out such measures, any more than the ordinary house occupier would be in a position to design his own water-carriage system. But it does follow that in appreciating what is involved in malaria control and having experience of some of the details of such work he is in a position not only to see it properly carried out but himself to do much to help. What may be called the high strategy of malaria control, such as the decision on the type of measure best adapted to particular circumstances is perhaps best left to expert advice, but there is a great deal that can be done by the planter, miner, or engineer himself in implementing such advice, and in this respect Dr. Macdonald's notes, giving as they do the essential facts the layman should know and a description of the different methods now in use, should be very helpful. Measures now mainly relied upon are various forms of drainage, dusting, spraying, and automatic petting with flushing devices for breeding-places; spraying, residual or otherwise, directed against the adult mosquito in houses and quarters; and, perhaps as important as any other measure, avoiding the creation of man-made breeding-places through ill-designed excavations, leaky water channels, and so on. In all these directions there is great scope for administrative talent, personal drive, and the inventive spirit. One small proviso might perhaps be stressed—viz., that it is essential that the layman who undertakes such work should be able to check up on the effect of what he is doing. For this he should be able to look for and recognize anopheline larvae in their natural breeding-places—not quite so simple a matter as sometimes made out, but one that nowadays could easily be learnt from a few hours spent with a collector or malaria officer.

Dr. Macdonald refers to the time when malaria was more severe in Malaya and affected industry more seriously

⁷ Clin. Sci., 1939, 4, 167.

⁸ J. clin. Invest., 1941, 20, 681.

man in any other country at an equal stage of development. Very largely by the efforts of planters and others engaged in industry this condition was brought to an end and Malaya became a model for other countries to follow. By the fortunes of war it has reverted to the state it was once in, though this can be remedied as it was before— but at this time without the need to accumulate new experience in the methods of doing it. The public spirit, initiative, and enterprise which before the war led to these results may, we feel sure, be counted upon again in the rehabilitation of Malaya; and, with what experience has been provided from the past, and the great advances in malaria control made during the war, there should be little doubt of the result.

ENVIRONMENTAL WARMTH

Maritime medicine has been much concerned with environmental conditions for nearly two centuries. For too long more attention was paid to machinery, equipment, and adjuncts than to the well-being and efficiency of the men. It was the usual story of the struggle of the machine versus man, interests which have conflicted since long before 1789, when Gilbert Blane wrote: "We see, indeed, infinite pains taken to prevent cordage from rotting, and arms from rusting; but however precious these may be as the necessary resources of war, it will not be disputed that the lives of men are still more so; yet, though there is the additional inducement of humanity to watch over the health of men, do not think that this, in general, is studied with a degree of attention equal to what is bestowed on some inanimate objects."

One important outcome of this war was a happy liaison between the Medical Research Council and the Admiralty—the Royal Naval Personnel Research Committee. The fruits of this union are even now inadequately recognized, but one of the most valuable is the recently published *Environmental Warmth and its Measurement*.¹ This memorandum, drawn up by Dr. T. Bedford primarily on the guidance of naval surgeons and such executives as the ventilation, construction, and gunnery officers, can be read profitably by all industrial hygienists. Two novel points are entailed in bringing up to date the science of environmental measurement: the use of special silvered data-thermometers, and the introduction of a new scale which Bedford terms the "Corrected Effective Temperature" scale. This differs from the original measurement devised by Yaglou and Houghten² in that globe thermometer readings are substituted for dry-bulb records. The reason for this innovation is the frequent occurrence in ships of unidirectional sources of radiant heat, which would detract from the accuracy of ordinary effective temperature measurements.

The late Medical Director General of the Navy, Sir Sheldon Dudley, writes a preface to the booklet, and a supplement gives a number of charts and nomograms. The monograph is not entirely devoted to the technique of environmental study, for one section deals with the effects of raised temperature upon output and efficiency and upon the accident rate. There is a useful bibliography, and special mention should be made of the excellence of the paper and printing.

TUBERCULOSIS IN TRINIDAD AND TOBAGO

In 1943 and 1944 Dr. W. Santon Gilmour was invited by the Colonial Office and the Council of the National Association for Prevention of Tuberculosis to carry out a survey of tuberculosis in the Colony of Trinidad and Tobago, the cost being shared as to £1,000 under the Colonial Development Act and £500 each from the Government of Trinidad and the N.A.P.T. Dr. Gilmour has now outlined in his report the tuberculosis problem in Trinidad and Tobago, placing it in its historical, racial, and economic setting.

The Crown Colony includes Trinidad, which is an island some 50 miles long by 37 wide, and Tobago, a narrow island 25 miles long, both situated a few miles off the coast of Venezuela. Descendants of African slaves introduced by the Spaniards, workers from India to meet demands of the sugar industry, with other descendants from Spanish and French settlers make up a varied total racial mixture of some half a million. Descendants of Indian settlers number about 200,000. The African predominates in the town, the Indian in the rural areas, the latter having the better housing: "From the point of view of tuberculosis there has not appeared to be any constantly direct relationship to nutrition other than malnutrition associated with poverty which still exists widely." The average temperature is not high for tropical areas, 69° to 88° F., but the average humidity is high, making the fatigue factor of much importance. The early tropical night also invites people indoors. Mortality rates from tuberculosis have been declining: 275 per 100,000 in 1896–1900 to 93 at the present time, which latter figure compares with 60 in the United Kingdom. Non-pulmonary tuberculosis is low in incidence. Very little milk is used, and most of it boiled before use. There is a much higher death rate in the towns compared with the country. Notifications about equal the deaths annually. Hospital and sanatorium accommodation is very inadequate. The tuberculin test was applied widely to give an indication of the infection rate and disclosed a high rate of infection in the towns and a considerably lower one in the country—and pulmonary disease was in the main found to be of the adult type. The Africans tend to present more acute than chronic disease; the Indians less disease, with tendency towards chronicity.

The main recommendations in the report concern the medical and nursing staff of the island; the provision of institutional accommodation and a few clinics. First, medical and nursing staff. These will consist of a whole-time chief tuberculosis officer and medical superintendent of a new institution, with the important suggestion that institutional work be unified in this one person undertaking clinic, preventive, and domiciliary work as is now done in the best schemes in the United Kingdom. Second, a sanatorium-hospital to be built up gradually to 268 beds, half for advanced cases. A site is already purchased and available near Port of Spain. The necessary additional medical and nursing staff are set out for the big sanatorium-hospital. Two new chief clinics are contemplated—one in Port of Spain, the other in San Fernando, with x-ray equipment. As regards diagnosis there has been a tuberculosis dispensary at Port of Spain working under the Trinidad and Tobago Association. It has been handicapped because (1) it is not officially recognized as the only place of reference of all cases of tuberculosis or suspected tuberculosis; (2) it is not the channel for admission of cases to the treatment wards of the existing hospital; (3) it has not the control of cases after discharge from hospital; (4) continued treatment after discharge from hospital and diagnosis have suffered from lack of equipment, especially x-rays; (5) the tuberculosis officer is part-time and has no control of notifications, or of admissions to hospital.

¹ M.R.C. War Mem. No. 17. London. H.M.S.O., 1946. Price 9d. (or including supplement, 2s. 3d.).

² *Trans. Amer. Soc. Heat. Vent. Engrs.*, 1923, 29, 163, and 1924, 30, 193.

The report makes many detailed recommendations for better and additional houses suitable to the special conditions of the islands. As a long-term policy better housing is required, and already the Government is dealing with the problem in some measure by its slum clearance. We are glad to note the Government proposes to enact legislation embodying the recommendations of the report.

UNITED STATES ARMY INSTITUTE OF PATHOLOGY

It was during the Civil War in 1862 that Surgeon General William A. Hammond founded the United States Army Institute of Pathology by ordering that pathological specimens be collected from hospitals and battlefields for the purpose of training Army surgeons. Seven months after its foundation the Institute had acquired thirteen hundred specimens illustrating wounds and the effects of projectiles. A year later a separate building had become necessary; and in 1887, the building in which it is now housed having been completed, the Institute's reports and specimens, together with the Surgeon General's Library (which to-day contains more than a million volumes), were established in Washington, D.C. Joseph Woodward started the photographic department in 1863. In 1942 its scope was greatly expanded under the designation of the Army Medical Illustration Service, and teams were sent to various theatres of war to take still and motion pictures in black-and-white and in colour, while some sixty general hospitals in the United States were equipped for clinical photography. The files now contain over a hundred thousand photographs in colour or monochrome and about a hundred thousand feet of cinematograph film. The Institute's present quarters have for long been inadequate, and it is hoped that they will soon be replaced by a new, enlarged Institute of Pathology and a thousand-bed hospital added, so that a centre for medical research and postgraduate training may be established for the study of the fundamental factors influencing disease. The staff consists of over thirty officers selected for their specialized knowledge, twenty Service men and women as clerical and technical assistants, and ninety-seven civilian employees. Information on any disease can be made available within a few minutes by means of sorting machines. Four departments have been formed: the Central Laboratory of Pathology, American Registry of Pathology, the Army Medical Illustration Service, and the Army Medical Museum. The director of the Institute is a Colonel in the Medical Corps of the Regular Army.

In accordance with the Federal Government's policy of sharing cultural and scientific matters with other nations the Institute aims at the dissemination throughout the world of knowledge of the pathology of disease. Its consultative service is available to foreign pathologists and medical graduates interested in special fields of pathology, as well as to the pathologists of the United States Army and American civilian institutions. The organization also conducts research into the pathology of disease and provides instruction in advanced pathology to officers of the Army Medical Department and others.

During the recent war Army hospitals in the United States and overseas sent in a wide variety of specimens, and it is expected that many more will be received as hospitals close down. Some of these specimens will be retained at the Institute, but it is intended that the surplus should be distributed to the war-damaged laboratories of medical schools throughout the world. Authorized foreign representatives and accredited scientists are invited to avail themselves of this valuable service. Further information

is obtainable from: The Director, Army Institute of Pathology, 7th Street and Independence Avenue, S.W., Washington, D.C., U.S.A.

INSECTS, MITES, AND ASTHMA

Allergic reactions to insect bites and stings are quite common and cause urticaria or angioneurotic oedema most frequently, asthma occasionally, and collapse and death rarely. It is less well-known that allergic reactions, especially rhinitis and asthma, may follow inhalation of insect emanations. The may-fly, sand-fly, house-fly, mushroom-fly, moths, and butterflies have all been incriminated.¹ Specificity has been proved, usually by conjunctival tests, passive transfer tests, and negative controls. Some of the case reports are of individuals exposed under special circumstances, but others are reports from parts of the world where the flies were present in myriads and the air was laden with the dust from the disintegration of their bodies. Such a report has recently been made by Ordtmann,² who describes asthma due to sewage flies (*Psychoda*) affecting workers at a South African sewage farm. The flies were so numerous that the shady parts of buildings and the interiors of homes near the filters were at times blackened by them. Thirty employees gave a history consistent with their asthma being due to sensitivity to the sewage fly, six showed positive skin tests to extracts of the fly, and two of the fly tested positive transfer tests; negative skin tests were obtained in controls.

The association of mites and asthma has in recent years aroused considerable interest, and was the subject of a leading article in this *Journal*.³ Attention was drawn to the findings of workers in Ceylon,^{4,5} that mites were present in the sputum of certain cases of tropical eosinophilia which was the subject of a recent annotation.⁶ This condition is also referred to as "eosinophilic bronchitis," "eosinophil lung," and "pseudo-tuberculosis." It appears particularly in India and Ceylon, and is characterized by asthma or bronchitis with an exceptionally high eosinophil count, and at times a particular x-ray appearance of the lungs; it is cured by arsenic. A second article by Carr and D'Abbrera⁷ describes their findings in twenty-five cases in Ceylon. Mites were detected in the sputum in every case, none had an eosinophil count of less than 3,000 per c.mm., and all except one responded to arsenic. The mites seem to live in the bronchial tree. It is suggested that they are responsible for the asthma and eosinophilia and that the arsenic effects a cure by their destruction. As the authors point out, further observations are necessary. It would be of interest to know whether mites occur in the sputum of apparently healthy people in Ceylon, particularly among those especially at risk.

There are both sewage flies and mites in this country. The former are localized to sewage plants but may be present in very large numbers. The possibility of individuals who attend to the filter plants being affected might be considered. That mites may cause asthma in this country appears clinically to be very unlikely, but more exact information from the entomologists of the conditions under which people are liable to be at risk is required.

We regret to announce the sudden death of Mr. A. Tudor Edwards, whose pioneer work in thoracic surgery won him international fame.

Reports of Societies

CONFERENCE ON AGEING

July 16 at the Imperial College of Science, London, a conference was held by the British Branch of the Club for Research on Ageing. The delegates of the European Branches of the Club and some other guests interested in the subject were also present. Lord Nuffield was elected Hon. President and Sir Francis Fraser chairman of the conference.

Sir FRANCIS FRASER, having introduced the delegates from ten countries, said that clinical research on old age was the most difficult of all fields of research as there were always so many uncontrolled factors to consider. Quick results were not to be expected. Pathological conditions were generally present in addition to old age. Clinical research on physiological ageing is practically impossible and it was better for clinicians to concentrate on studying primarily the pathological conditions. Prof. F. A. E. CREW gave an account of recent work in Holland on the sociological problems of an ageing population. The current figures for births, deaths, and marriages appeared satisfactory on the surface, but when looked into more carefully the present population trend showed a most disquieting increase in the proportion over 65. Since industrial capacity diminished after 35 there was a danger of the old becoming a burden on the young. He urged the need for closer collaboration between clinical investigators and those working on population research. The real problem of gerontology was "not how to give years to life, but life to years."

Dr. M. CRITCHLEY urged the need for further research on the nervous system in the study of normal ageing as well as the associated pathological conditions.

Dr. V. KORENCHESKY expressed the aim of gerontology as not merely to achieve a longer life but a stronger one. Since ageing started at a very early age they must include the study of the whole life span and even the development of the foetus. Attempts at rejuvenation by such methods as Voronoff's grafts, hormone treatment, or Bogomoletz's serum were unsatisfactory since they achieved only a temporary stimulation. The aim must be to discover and remove the causes of premature ageing and not merely to stimulate degenerated tissues.

Prof. F. C. BARTLETT considered that the effects of ageing on psychological performance could be compared with the effects of other factors such as extremes of heat, humidity, and noise. Each of these produced an increased liability to fatigue, which could be measured in a number of ways. New methods developed for the study of skill and fatigue in air pilots during the war might be applicable.

Reliable Information Sought

In the discussion which followed Prof. G. R. CAMERON emphasized the need for quantitative research on the effects of ageing on the blood vessels of the brain; there was scope for the employment of many new techniques on this problem. Lord Nuffield said he could not understand how ageing could begin in early childhood, since the athletic performance of a child went on improving up to the age of 15. Dr. Korenchewsky and Dr. Hammond pointed out in reply that different organs developed at different ages: brain and bone had priority at an early age and muscle developed only later. Prof. M. J. STEWART wanted research to be carried out on changes in the blood in old age. Many old people died of pneumonia because their blood failed to respond as vigorously as that of young people to the toxins of the pneumococcus. Dr. D. RICHTER urged the need for more accurate statistics of the causation of death. The present figures were unreliable as permission for a necropsy was often refused. The public must be educated to a realization of the importance and value of post-mortem examinations. Dr. L. FAIRFIELD deplored the way in which the chronic sick and aged were despised by the teaching hospitals and thrust on the public authorities. Medical science had relieved many of the worst miseries of old age, but senile dementia was a social problem of increasing urgency. Was it right that healthy young women, who should be bringing up

children in their own homes, were engaged in washing the dirty linen of wards full of wet and dirty senile demented?

Dr. PURCHASE, as a coroner, agreed as to the unreliability of the present statistics and said he could provide reliable figures for some two thousand cases a year on which necropsies were carried out. Prof. Crew said he was anxious to close with Dr. Purchase's offer. Dr. Fairfield considered that the conspiracy among general practitioners to avoid putting cancer on death certificates might cause significant error in the figures.

The morning session was closed by the passing of five resolutions expressing the requirements for the further advance of gerontology. These included international co-operation between those interested in the subject, establishment of permanent institutes for research on ageing, and the provision of ample funds necessary to secure these facilities.

Hormones and Ageing

At the afternoon session Dr. Williams read a paper for Prof. E. DODDS on the significance of androgen and oestrogen excretion in the urine in relation to ageing. The tendency to cancer of the prostate was considerably affected by the sex hormone balance as shown by experiments on castration and by the effects of administering stilboestrol in the male. Prof. Crew pointed out that the male infant had a much poorer chance of survival than the female. A male infant with bronchopneumonia was thus suffering from two conditions: (a) bronchopneumonia and (b) maleness. Could we use sex hormones to transform temporarily a male infant into a female to get over this disadvantage? Dr. Hammond, describing recent work at Cambridge, said that chronological age must be differentiated from physiological age. The physiological ageing of the foetus could be varied experimentally by controlling the size of the litter and the nutrition of the mother. Similar factors might operate in the return to an infantile condition in old age.

Prof. J. B. DUGUID put forward a new theory of the thickening of the arteries in atherosclerosis. We had been misled by the teachings of Virchow. The thickening did not come from within the artery walls: it was due to the organization of successive layers of fibrin deposited on the intima. In his view the primary cause of the disease was in the blood rather than in the vessels. Prof. Cameron asked how this could account for lipoids in atheromatous plaques. If the arterial narrowing was due to encrustation with fibrin from without, why did not the veins get narrowed in the same way? Prof. Duguid felt the relation of lipid changes to atheroma was not fully understood. The veins did not get narrowed, because when they thrombosed the whole vein became blocked, while in an artery the vessel was cleared by the rapid flow of the blood.

Dr. Korenchewsky gave an account of experiments on the artificial premature "climacteric" and its effects on ageing in female rats. Ovariectomy hastened ageing of rats. The combination of androgenic, oestrogenic, and thyroid hormones produced an apparent "anti-ageing" effect as judged by the organ weights and histological appearances, but this might be a temporary stimulation of ageing organs.

Effect of Vitamins

Dr. W. STEPHENSON read a paper for Dr. P. E. VERNON in which it was concluded that large amounts of vitamins exerted little effect on psychological ageing when the diet was adequate in these compounds. Dr. Stephenson described some work of his own in which an increase of vitamins in a diet previously deficient in them had improved the mental capacity of senile subjects. Prof. Bartlett criticized the use of psychometric tests in these experiments: the performance of such tests was not characteristic of senile subjects; the things that they normally enjoy doing should be measured.

Dr. RICHTER described an investigation of the biochemical changes. Mental and physical deterioration in ageing were processes that could be differentiated by their biochemical accompaniments; the changes associated with senile dementia were different again. Senility was a series of pathological processes which needed to be more clearly defined. Much public money was now being spent in providing homes for old people: there was an urgent need that more should be spent on preventive measures, which meant research.

Dr. J. H. SMYLY gave an account of his methods for assessing physical fitness in old men, including exercise-tolerance tests

as measured by pulse rate and oxygen consumption. The usual methods might be dangerous for old people.

Prof. Crew in summing up said that the proportion of old people in the population was increasing, and gerontology was therefore of increasing social importance. He recommended the formation of a permanent International Congress Committee to organize international gerontological congresses.

Nova et Vetera

SIR DOMINIC CORRIGAN

Nos. 1 and 2 of Volume VIII of the *Dublin Historical Record* contain an interesting memoir by Dr. Eileen Dixon of Sir Dominic Corrigan, who described the "famine fever" of 1847, wrote upon diseases of the heart, and in 1832 published an original description of insufficiency of the aortic valve. His name lives in the characteristic "water-hammer pulse" of aortic regurgitation.

Dominic John Corrigan was born in Dublin in 1802, one of six children. He went to school at the Lay College of Maynooth, a separate institution from the Ecclesiastical College, though the boys were not kept apart too rigidly. His classical grounding stood him in good stead when later he attended medical lectures in Latin at Sir Patrick Dun's Hospital. After qualification he became known as a sound and popular lecturer in the medical schools. His practice was enormous and for many years very lucrative. After an early failure, due to party and religious spirit, he was elected a Fellow of the Royal College of Physicians of Ireland in 1859 and soon afterwards began a term of five years in succession as its president. He was for a time Member of Parliament. Honours flowed in. For the first time in history a Catholic was appointed Physician-in-Ordinary in Ireland to Queen Victoria, and two years later, in 1849, Trinity College conferred an honorary degree of M.D. upon him. He was a member of the General Medical Council from the time of its foundation in 1857 until his death in 1880. But perhaps, as Dr. Eileen Dixon says, the distinction that he himself may have appreciated most was his election as Corresponding Member of the Paris Academy of Medicine in 1874, an honour only once previously bestowed on an Irishman, Richard Carmichael. For four-fifths of his working years Dominic Corrigan was one of Dublin's famous Merrion Square doctors. He was created a baronet in 1866.

MEDICAL ASSURANCE

The annual general meeting of the Medical Sickness, Annuity and Life Assurance Society, Ltd., was held for the first time at its new offices, 7, Cavendish Square, on July 16, Mr. R. J. McNEILL LOVE presiding.

In his address, Mr. McNeill Love made some reference to the National Health Service Bill. "We welcome any steps which might improve the service which our profession gives to the community, but we are not convinced that the suggested measure will secure the results. There is no doubt that very many doctors resent the able limitation and control of their work, and they are uneasy at the future. This state of mind is not improved by the realization that the eventual aim of the Government is to establish a full-time salaried service."

Turning to the accounts for the year, the Chairman said that in the Life Assurance Fund new business at £270,048 showed an increase of £45,208 on 1944; and the total annual premium income was now £175,431. Claims by death and maturity were over £80,000, which was a very large increase on previous figures. In the Sickness Fund the premium income was now £135,366, and claims paid during 1945 were £72,265—actually less than in 1944, although the amount at risk was substantially higher. The funds of the Society had increased by £200,000, and now amounted to £3,226,000.

Sir Cecil Wakeley, who was congratulated on his recent honour, and Mr. Bertram Sutton were re-elected directors. The meeting agreed to an interim bonus on with-profit policies for permanent sickness and accident insurance and life assurance terminating at the stated age or by death in 1946, the bonus on life assurance to include provision for each of the years since the valuation in 1936.

Imperial Chemical Industries has leased the house and laboratories at The Frythe, Welwyn, Herts, for conducting long-term research into such subjects as the antibiotic products of moulds, kinetics of continuous chemical reactions, and industrial design and toxicology. Work has already begun, but this accommodation will be temporary and will be used until a site near St. Albans can be developed.

Correspondence

Health Service Bill

SIR,—The National Health Service Bill has now been discussed from every conceivable standpoint, and there are few medical men who are not well versed in its provisions. Professional opinion seems to be divided into four main groups: (1) Those who for political reasons strongly support the Bill; (2) Those who, having little or no experience of general practice and lacking economic security, support the Bill for its obvious advantages for themselves; (3) Those who have been compelled for some years to submit themselves to the rigours of general practice and who, heartily disliking many of the provisions of the Bill, feel that the profession should accept it in the same spirit as the tired doctor accepts a night shift; (4) Those who object to the Bill on a basis of principle regardless of its advantages or disadvantages to themselves. The fourth group has not been very conspicuous—probably because it is very much easier to know that a thing smells bad than it is to give concise reasons why it does so.

Since the Bill is called the National Health Service Bill it is presumably to be judged by the degree of service which it provides for the general public. The advantages or disadvantages which accrue to the consultant or the general practitioner are therefore of secondary importance.

Regarded in this light two important facts emerge: (1) Adequate service can be given unless the amenities in the staff of hospital beds and staffs are forthcoming. (2) The medical profession has two distinct services which it renders to the general public: (a) a personal service rendered by the general practitioner; (b) an expert treatment-of-disease service rendered by the hospital and the consultant.

The hospitals, which started as institutions for the treatment of the sick poor, have developed into institutions for specialist treatment of disease. Mr. Jones in the medical practitioner's surgery becomes No. 14 in the hospital ward. A specialist is not a specialist in human nature but a specialist in some specific group of diseases. Where the medical practitioner treats the whole person the hospital and the consultant treat his disordered function.

Now, the State through its Government deals not with individuals as such but with their functions. The various shades of political opinion vary from a right wing which, while legislation for man's functions, recognizes that he has an individuality which should be given expression, to a left wing which regards man as a functioning citizen and nothing else. When, therefore, the State takes an active interest in the health of people it can legislate for man's disordered functions, but cannot and must not interfere with his individuality. This has very important implications in relation to the Bill. It means that, taking a long view, the general public will get an ever-improving service from the consultant and the hospital but continually deteriorating service from the general practitioner. This fact has nothing whatever to do with the willingness of the professional man to work the Bill or with his efficiency or skill.

It seems likely that the medical profession will be split into two sections on this point. The long-sighted consultant will see that he will have an ever-increasing opportunity to do good work, while the equally long-sighted general practitioner will see that purely clerical duties will absorb more and more of his time. There is much in the hospital and consultant service which will benefit from State interference. There is nothing in the general practitioner service which cannot be improved without the State interfering—I am, etc.,

Bath.

E. R. MATTHEWS

SIR,—Every doctor will agree with the first sentence of Dr. McIntosh Rattray's letter (Aug. 17, p. 238), but with his interpretation of Dr. Dain's address, as reflected by his subsequent remarks, there will not be such unanimity. While we all admit the difficulty of getting every single doctor to make up his mind, that is just what Dr. Dain told us to do. "Where do we stand?" he asked. "This decision has to be made, by the medical profession as a body or acting through

The
complementary
treatments
for colds

THE therapeutic properties of both Silver Vitellin and natural levorotatory Ephedrine are well known. In Argotone they have been successfully combined into a *stable solution* in normal saline, providing disinfection and decongestion in the treatment of nasal affections.

In the common cold there are other distressing features—headaches, stiffness and fever. To relieve these symptoms the oral administration of Deltamin tablets is recommended.

Together, Argotone and Deltamin offer a complementary treatment for the common cold.

ARGOTONE + DELTAMIN
NASAL & EYE DROPS TABLETS

FORMULÆ

ARGOTONE: Silver Vitellin 1%, Ephedrine 0.9% in Normal Saline.
DELTAMIN: Aspirin 7.70 grains, Ephedrine hydrochloride 0.30 grains.

MIGRAINE

Clinical experience of recent years has provided ample proof of the fact that no other drug has given results so uniformly successful as FEMERGIN (Ergotamine tartrate) in the treatment of migraine. Even patients who have long been subject to migraine attacks have in the majority of cases obtained almost miraculous relief following the administration of FEMERGIN.

The dosage should be the minimum that will be effective, generally 0.5 c.c. by hypodermic injection will suffice to avert or cut short the attack. In resistant cases the dosage may be increased up to 1 c.c. In mild cases oral administration of 2-4 tablets, preferably sublingually, may provide satisfactory relief.

Tablets of 1 mg. Ampoules of $\frac{1}{2}$ and 1 c.c. containing 0.25 mg. and 0.5 mg. of ergotamine tartrate.

ouncil, but by each individual member of the profession . . . ere comes a moment at which the doctors themselves must e asked what action they intend to take. The Council will t on their instructions. . . ."

Our course has not been set for us. The future policy is to e decided by each one of us by himself in his or her own ome. As a profession we are accustomed to taking decisions of ome magnitude every day of our lives, and I agree that we ould not sit on the fence any longer. The sooner the plebiscite aken the better. Until the result is known no action can be aken, and the present battle of words will continue. It ill ecomes one who loves freedom to call his colleagues traitors. here is to be no conscription into the Service, and those that o not like it can stay out, and not even Mr. Bevan will call hem traitors. Why therefore apply the epithet to those who ay wish to join the new Service? And who knows?—they ay even be in the majority.

There is no danger of the medical profession becoming ex-inct. The need for our art grows yearly, just as the need for strong and united B.M.A. grows more vital as the weeks go y. There has been too much verbal bickering, and it does us o credit with either the public or the Minister. Once the esult of the plebiscite is known let us all unite behind the Council in following a common line, and let there be no more alk of traitors nor of dishonourable conduct. The debate has gone on long enough. The time for a vote has come. Which- ever way it goes let us hope that it will be decisive.—I am, etc.,

Skewen.

TREVOR DAVIES.

SIR,—The Minister of Health, a paid public servant, demands o have supreme power conferred on himself and his successors, power which sets aside the jurisdiction of the High Court of Justice—this and nothing less will satisfy his craving for authority. So far, by political acumen, astute handling, with an arrogance seldom exceeded, and backed by a heavy "yes-men" vote a totalitarian measure has been forced through the House of Commons on the highly debatable pretext that it is the-wish of the people.

In actuality the informed public are antagonistic to this Bill ; the as yet uninformed will thank the medical profession if it insists on a much more detailed consideration of the implications of this extremely complex measure before signing away its liberties, together with those of the people, and abjectly "bending the knee" to the dictation of any one man. To sign a service contract must mean complete failure to recognize the "iron hand in the velvet glove," but at the same time it means blind and trusting acceptance by the signatory of what is acknowledged in every quarter to be merely a "skeleton Bill"—but nevertheless when fully garbed a political weapon of quite unlimited potentialities.

A brief résumé of the "conditioning process" to which the medical profession has been and still is being subjected may help to throw into relief political ethics. The blending of dulcet tones to attract the young by spurious promises of initially attractive salaries, the more-than-market value offered for practices to induce the older men to part with their freedom: these ill conceal the ulterior motives behind this seeming generosity. Through State seizure of hospitals (plus their endowments) consultants either sign or starve; by abolition of the right to buy or sell the general practitioners likewise have duress applied; thereafter each will be directed or controlled.

Fate has placed on the shoulders of the medical profession a very heavy burden of responsibility to the people of this land, for on the decision to steadfastly decline to be a party to bribery and corruption is poised the fate of a nation—here surely is the chance to strike a blow to free an "England in Prison." Count well the cost before bartering your soul, your independence, and your self-respect for specious promises of materialistic gain, for which in any case there are no honest guarantees but only memories of broken pledges (reduced capitations, raised insurable income limits, broken E.M.S. contracts).

After a calm survey of such a record can you trust the politician? Would it not be wiser to use your own common sense in conjunction with your conscience before signing?

This Bill as it stands is totalitarianism naked and unashamed. If we have moral principles and do not exercise them fearlessly this "skeleton" will see to it that the opportunity for so doing will never again arise: we shall have reaped where we have

sown. The plebiscite will at least determine whether in the main we are morally sound or rotten with corruption and unworthy of the responsibilities we have to carry. It surely is not so. In short, we are being tempted to barter our freedom and our honour for economic baits.—I am, etc.,

St. Ann's-on-Sea.

G. H. URQUHART.

SIR,—I would like to congratulate Dr. C. G. Jones (Aug. 17, p. 239), who has, I feel quite sure, expressed the views of a large section of our profession. The report of the Annual Representative Meeting made very sorry reading: I refer particularly to the speech by Dr. H. Guy Dain, the Chairman of Council, speaking on behalf of the Council. It is a fundamental law of nature that there shall be opposition to every growing, developing thing. It is more than regrettable that the opposition to the National Health Service Bill has come from the leaders of our Association. The B.M.A. has already said and done quite enough to be made the laughing-stock of future generations of doctors, who will be, as Dr. Jones rightly states, doctors because of their vocation and not merely business men being doctors.

Week by week we are urged to unite to "fight the Bill," to "fight the Minister," to "bring the Government to its knees," and Dr. Dain concluded his speech by saying that "we are in the strongest possible position for ensuring that what we think is best for the public will be carried out." What rubbish! There can be no such unity. An appreciable number of doctors see in this Bill the way to better health for the people of the British nation, and no amount of claptrap will deter them from working in the new Service to the best of their ability. It would appear that some members of our profession require a reminder that we are in fact living in a democratic country, which implies in our case government by an elected majority in the House of Commons. The present Government, elected by constitutional methods in 1945, has decided that there shall be a National Health Service and has laid down certain basic principles upon which the Service shall be built. Let there be no mistake—the new Bill will be on the statute book in the near future. With the full co-operation of the profession the new Service could be second to none. Without that co-operation it might well be a mediocre apology for a Service of which nobody could be proud. It does not require a great deal of thought to see where our duty lies.—I am, etc.,

Scarborough.

PETER WADDINGTON.

SIR,—Judging from most of the correspondence and articles in the *Journal* it would appear that some members of the profession at least do not approve of the proposed National Health Service. This is of course a pity. The main complaints appear to be directed against the ministerial powers—his power of direction—and the fact that we will become a salaried service.

The direction of doctors appears to me to be an unfortunate but very necessary evil. It will be impossible in the future, as in the past, to spread the limited number of doctors evenly throughout the country without some sort of planning. Without control there would inevitably be areas of relative congestion and sparsity. Surely we can see that this is so and therefore agree that some measure of direction is required. Is it not the *method* of direction rather than the *principle* of being directed into which we should inquire? Providing the "direction" is reasonably carried out, with due consideration being given to the preference of doctors for the type of work and areas in which they wish to work, nothing but good can result. This will I believe prove to be the case.

The proposed National Health Service is a magnification and improvement on an already well-tried and successful system—the Panel. No one can deny that this system is not a good one, and that should there be any failure in the ability of doctors to work an extension of it (i.e., the National Health Service) perhaps the fault lies not in the system but in those who have to work it.

Ministerial powers can of course become dangerous. Again, rather than strive to fight the principle whether or not he should have these powers should we not grant that he must have them but see that the powers are not carried beyond those given to him by Parliament, which, under an excellent democratic system, represents the wishes of us all?—I am, etc.,

London, E.2.

ALAN MALCONE.

Principle 2 and the Health Service

SIR,—Two distinct issues seem to be involved in the choice of a right medical policy at the present time. The first involves the question of the manner in which the best possible Health Service can be provided within the terms of the Health Bill having regard to the number of available doctors, the number of patients to be provided for, and the amount of money to be spent upon the service, and so on. This first issue has been under debate for years. The B.M.A. has tried to persuade both doctors and the public to set up a complete service based upon existing and established services. Any chance of success these proposals may have had was destroyed partly by the absence of enthusiasm among doctors for any radical change and partly by the results of the last election.

It is now clear that the community has decided the general form of the Health Service that it desires to have. Hence only one choice lies before every doctor: to accept or to refuse service under the Act in 1948. Before he can finally make this choice every doctor must determine his attitude towards accepting service in any State-conducted Service. When he has done that he must ask himself whether the actual conditions of work and remuneration are likely to be such that he is willing to accept service. If his answer to either of these questions is in the negative he will know where he stands. But even if he is prepared to accept service in a State-sponsored Health Service he will still need to be satisfied about the conditions of work that will be offered to him in the Service.

This brings me to the second issue. The conditions of work under the new Health Bill are only partly determined by the Bill itself. Many of them will be determined by the Regulations that are yet to be made. It seems to me to be most impolitic to attempt to precipitate a struggle about a short-term issue such as the amount of the present N.H.I. capitation fee. What we ought to be discussing are the long-term issues—I mean remuneration and conditions of service—so far as they will be settled by Regulation. I see no reason why such a discussion cannot be "without prejudice" on both sides. One thing at least is certain: many doctors will not be able to decide whether they are willing or unwilling to enter the new Service until they know a great deal more about the proposed conditions under which they will be asked to work. As soon as those conditions have been made clear we shall be able to make plans for our future with some degree of certainty.

When the Act is in operation we may find in fact and in experience that it infringes Principle 2 in some important respect. If that happens the time will have arrived for a real trial of strength. If the above plan of action should prove to be generally acceptable to the profession we should not place ourselves in the invidious position of appearing to be seeking to force the political views of a majority of doctors against the expressed will of the community. If only a tithe of the warnings given by some doctors should prove to be justified it will not be long after Jan., 1948, before we have strong grounds and wide popular support for a demand for changes in the Regulations or even in the Act itself.

In my opinion Principle 2 is the only solid ground on which opposition to the new Service can be rightly undertaken, and that only after the Act has been given a trial.—I am, etc.,

Worcester

HOWARD E. COLLIER.

* Principle 2 is as follows: "The medical profession should remain free to exercise the art and science of medicine according to its traditions, standards, and knowledge, the individual doctor retaining full responsibility for the care of the patient, freedom of judgment, action, speech, and publication, without interference in his professional work."—Ed., *B.M.J.*

Direction in National Health Service

SIR,—I cannot see how a National Health Service can be run efficiently without a certain amount of direction. After all, do we not have a degree of negative direction at present? When a man qualifies in the ordinary way he applies for a hospital appointment or an assistantship. Obviously he must apply where there is a vacancy, and if that is just where he wants to go then he is lucky. It appears to me that under the N.H.S. these conditions would be similar.

There are at present certain districts in large towns which are insufficiently supplied by medical practitioners. Conditions in these areas are not attractive, and therefore at present shunned, but under the N.H.S. they could be made more attractive by carrying a higher rate of pay. You can always get a job done if you pay highly enough, and this can be done under a Service, whereas it is impossible under present conditions of practice.—I am, etc.,

Portsmouth.

DOUGLAS W. BRUCE

Negotiators and Legal Advice

SIR,—I should like very strongly to support the letter of Geoffrey Dudley (Aug. 17, p. 240). It has always appeared to me that the very best legal counsel should be employed in negotiations with the Government, and I have always been surprised at the apathy of our profession in this matter. I once raised the question at a B.M.A. meeting at which members of the Central Executive were present, but there was a complete absence of any acknowledgment that the idea was sound. I am, etc.,

Richmond.

R. K. ROBERTSON.

SIR,—Surgeons and well-known consultants will float easily above the murky waters which will engulf the free profession. It is high time that a strong Committee of Finance controlled dealings with the Socialistic Government, which daily is becoming more totalitarian than ever. An experienced lawyer should hold the chair. Salaries, capitation fees, retiring pensions, and a definite arrangement for the distribution of the promised £66,000,000—the solatium for the life work of thousands of busy doctors who on a wave of the hand are renouncing all dealing in their property—all need deciding at an early date. Once on the statute book repealing or amending is a troublesome matter. The profession owes a debt of gratitude to Mr. H. U. Willink.—I am, etc.,

Cranlock.

A. L. MARTYN.

Amoebic Dysentery

SIR,—I have recently been able to read the letters and articles which have appeared in the *Journal* discussing at some length the condition of amoebic dysentery. While most of them pointed out that this chronic condition could cause manifold different symptoms only one such symptom appears to have been mentioned—i.e., that of diarrhoea.

It became apparent to all medical officers working in the Far East that many common symptoms of this condition have as yet not found their way into the textbooks. The hazard to the general well-being of the population of this country in relation to the large number of men and women returning from the Far East has been well recognized, and in this connexion it is interesting to note that at Service hospitals to which men are medically repatriated for reasons other than amoebiasis a routine tropical overhaul reveals a large number of apparently symptomless patients who are infected with amoebic cysts. An even larger number must by now have taken their place among the civilian population.

The general practitioner is bound to be confronted with such patients, and unless he is aware of at least a few of the more common symptoms with which such patients present themselves proper investigation may be dangerously delayed.

(1) Diarrhoea is the commonest symptom, and even in this country it may be of an acute nature, although more usually the patient complains of persistent loose bowel actions with or without blood and mucus. Such conditions are seldom missed.

(2) Pain in the abdomen. Acute abdominal pain in any patient who has spent some time in the East should be regarded as an "amoebic possibility": often these patients even without fever have a liver or caecal infection with *Entamoeba histolytica*. Persistent dull abdominal pain with apparent good general health is probably one of the more usual manifestations of this disease that the general practitioner sees in this country. It resembles closely the symptomatology of peptic ulceration, and is accompanied by a large excess of large-bowel flatulence which is most embarrassing to the unfortunate sufferer. Chronic caecal pain may again be a pitfall in diagnosis; and in both these cases widespread pin-point bowel mucosal lesions discharging amoebic cysts should be excluded.

(3) Haemorrhoids. The number of people who report to their doctor with piles is enormous, but in any fresh cases the doctor may be in men or women returning from the Far East it is as well to include the possibility of amoebic bowel ulceration as the primary cause of the condition.

(4) Malaise and irritability. The general practitioner is overwhelmed by patients complaining of general debility; but clinically it is of interest to note that the stools of patients giving past history of overseas service, often a history of very vague abdominal discomfort, and complaining bitterly of continued irritability for which they cannot account will often demonstrate amoebic cysts. The chronic civilian sufferer from amoebiasis in the East always states he knows when he is due for a relapse by the onset of this odd irritability.

This list is by no manner of means complete or comprehensive, but it may afford the already overworked practitioner a basis on which to work.

This letter was prompted by the fact that I have recently seen in this country two cases: one "operated on for piles which had persisted" who showed large ulcer craters with actively motile *E. histolyticae* three inches above the pile-bearing area; and the other investigated for flatulent dyspepsia and discharged with negative results who had large numbers of amoebic cysts in his stools. Appropriate treatment cleared both these cases.

I feel sure there must be many more such patients.—I am, etc.,

London, N.12.

M. L. MASON.

Transurethral Prostatectomy

SIR,—I do not wish to join in the present battle of words taking place in your columns on the relative merits of the transurethral versus the open prostatectomies, but I must refute the inaccurate figures and erroneous conclusions drawn therefrom contained in Dr. H. T. Cox's letter (Aug. 17, p. 241). If Dr. Cox will carefully re-read my paper (*Proc. roy. Soc. Med.*) to which he refers he will find the 219 cases of resection reported herein did not represent my total but merely a group in a consecutive series of 357 cases dealt with by various methods. I have been performing transurethral resection of the prostate since Sept., 1931 (*Lancet*, 1, 121; 1932, etc.), and have carried out more than 1,600 such operations. I think by now I can claim to appreciate that the procedure has very definite contradictions quite evidently not realized by some of the recently converted ultra-enthusiasts.—I am, etc.,

London, W.1.

TERENCE MILLIN.

The Catheter and the Prostate

SIR,—Mr. Wilson Hey (Aug. 17, p. 241) reiterates his well-known statement that operation must be delayed if a catheter has been passed for prostatic obstruction. In the last paragraph of his letter he condemns suprapubic cystostomy as a dangerous procedure. It would be of the greatest help to both general practitioners and surgeons if he would state categorically what should be done for a patient when acute obstruction supervenes on chronic under conditions when transfer to hospital or nursing home involves considerable delay. This is a common experience for many. He should also make it clear how such patients are to be treated after their initial obstruction has been (perforce) relieved by catheter pending operation.

Mr. Wilson Hey may have made these points clear in previous correspondence, but I have been unable to find it, and apparently many others are in the same difficulty.—I am, etc.,

Belfast.

C. J. A. WOODSIDE.

Reiter's Disease

SIR,—I beg to draw attention to the fact that so-called Reiter's disease, as described by Flight-Lieut. W. P. U. Jackson (Aug. 10, p. 197) and Dr. F. Wrigley (p. 199), is almost certainly dysenteric polyarthritides, as it is well known to most physicians who served in dysenteric zones in the Hitlerian war. A history of dysentery, sometimes fleeting, with a latent interval of about ten days could be established in nearly all the cases I saw (about a dozen), and in no instance was it the first attack. Paulett and

I succeeded in reproducing the sterile conjunctivitis by instilling a drop of Flexner vaccine into the conjunctival sac in three of these cases, the flare taking place after an interval of five to eight days. It was impossible to employ autogenous vaccine because stool cultures were always negative when such patients were first seen, and it was therefore a matter of chance whether we used the right organism or not. Conjunctivitis did not follow use of the vaccine in normal controls, nor in patients with gonococcal polyarthritides or with streptococcal polyarthritides (rheumatic fever). Vaccine dropped into the urethral orifice in several cases failed to cause urethritis, however. Vaccine dropped into the conjunctival sac of cases of dysentery without polyarthritides yielded essentially negative results. This work was not published owing to loss of the records in Italy (in the usual way).

The hall-marks of the various organisms responsible for different forms of what is thought to be allergic polyarthritides are interesting: conjunctivitis and urethritis (sterile) point to the dysenteric group; tenosynovitis to the gonococcus and tubercle bacillus; carditis and salicylate response to the streptococcus. The list is by no means complete, and the explanation remains unknown.—I am, etc.,

London, W.1.

PAUL WOOD.

SIR,—You published in the *Journal* of Aug. 10 two interesting short papers; one by Flight-Lieut. W. P. U. Jackson; the other by Dr. F. Wrigley, on Reiter's disease. I entirely agree with their view that this syndrome should be more widely recognized, both in order to promote further research into its aetiology and to remove an unjust stigma of venereal disease from certain cases. At a discussion on acute arthritis in adults, held by the Physical Medical Section of the Royal Society of Medicine in April, I drew attention to this condition, giving brief notes on six cases seen in the Middle East and suggesting that some of the cases discussed at the same section in 1942 by Lieut.-Col. King and myself as being probably of gonococcal origin might more rightly have been classified in this group. By 1944 Lever and Crawford were able to find 45 such cases in the literature.

The order of appearance and time lapse between the appearance of the symptom triad vary a great deal, but I think it unusual for the urethritis to appear thirteen days after the arthritis as in Case 1 quoted by Jackson, and again the presence of a true keratitis described in Case 3 is, I believe, uncommon. The most likely aetiological agent appears to be a virus of the Waelsch type, which is probably also responsible for "swimming bath" conjunctivitis and "inclusion" cervicitis (Van Rooyen). Research into the causative agent in this syndrome is urgently required, and valuable information may be obtained by careful recording and follow-up of suspected cases, together with examination of urethral scrapings for inclusion bodies and the carrying out of the Frei antigenic reaction. This was unfortunately impossible in my cases, but under peacetime conditions it should be less difficult.—I am, etc.,

Bath.

SIR,—After reading the article on Reiter's disease by Flight-Lieut. W. P. U. Jackson (Aug. 10, p. 197), one is reminded of the fact that the triad of symptoms described is a well-known complication of bacillary dysentery. Although the author states that "diarrhoea, sometimes severe and bloody, may be present at the onset," no mention is made of bacillary dysentery as a possible aetiological factor in his cases. Complications in bacillary dysentery may occur during the attack, but the usual story is that they occur two or more weeks later, and unless a history of diarrhoea is inquired for the patient will rarely volunteer the information. The author used sulphathiazole in treatment, and it is of interest to note that following the introduction of sulphaguanidine in the treatment of bacillary dysentery the incidence of complications became negligible.—I am, etc.,

St. Helena.

JAMES KAY.

Problem of Haemophilia

SIR,—I was much interested in the annotation on the problem of haemophilia (July 6, p. 18) and the treatment of this condition with plasma. In discussing the causation and treatment of this condition (*Clin. J.*, 1936, Dec.), I referred to Howell and Cekada's researches which indicated that the platelets were unduly stable and, therefore, thrombokinasase was liberated so slowly that clotting was unduly delayed. I also pointed out that bleeding occurred without trauma.

Since 1942 I have treated seven cases of true haemophilia and two cases of multiple hereditary telangiectasis with plasma applied topically and by mouth—seemingly with good effect. The usual method has been to give from one to two measured ounces of plasma three times a day and also regularly as a prophylactic measure. This seems to have been very helpful, and where the full dose of plasma has been continued the patient has been practically free from bleeding.

For some unknown reason the improvement in the coagulation time in the blood frequently does not coincide with the marked clinical improvement which ensues. It is important to note, however, that there are factors in haemophilia which are not understood—such, for instance, as the undoubted periodicity which occurs in some cases; and it is possible that there is also a capillary factor which has a direct action on the walls of the capillaries, quite apart from the alteration in the coagulation time. While evidence has been adduced that the unduly stable platelets of haemophilic blood break down normally when in contact with normal plasma, it is possible that much more normal plasma may be required to liberate sufficient thromboplastin to bring about normal coagulation than is required for the liberation of the capillary factor, if this exists.

The most striking case was a man who recovered after amputation of the leg for a compound fracture of the femur, which had become septic. This patient had been under my care, having prophylactic plasma for over a year, and during that time he had been much improved. He gave a typical history of haemophilia, and the blood-coagulation time was characteristic. The family history revealed that one cousin, two maternal uncles, and one maternal great-uncle had all died from haemophilia. Unfortunately the patient sustained a compound fracture, and when I saw him some weeks later two open sinuses were oozing blood and pus continuously, while huge masses of septic blood clot extended up the thigh. As would be expected the patient was very anaemic and cachectic. After ordering transfusion I expressed the clot through the sinuses by manipulation over two or three sessions. The wound was gradually cleaned by irrigation with peroxide and hypochlorite solution, and the application of sulphanilamide. It continued to ooze, however, despite transference because the sharp ends of the fractured bone, which were art, caused frequent trauma. I consulted with my colleague, Kenneth Pridie, and he agreed that the only hope of saving patient's life was to undertake the formidable procedure of amputating the leg. This was successfully performed by Mr. Isserlin, the patient being transfused before and after the operation. At first all went well, but some days later I was asked to see him again as the stump was septic. The sutures had broken down, and underneath was a mass of foul-smelling, septic clot which oozed continuously. I removed masses of the septic material with my gloved hand, swabbed with peroxide until the stump was clean, then applied dressings soaked in plasma, which were successful in stopping the haemorrhage. I ordered another transfusion and also a combination of bipp and plasma to be applied to the wound. This was very effective; and when it was quite clean skin-traction was applied by Mr. Isserlin, and the wound was successfully sutured. All this time the patient had several transfusions, and 2 oz. (57 ml.) of plasma in milk by mouth, i.d.s. He was eventually discharged from the Bristol Royal Infirmary quite well. Since then he has taken the plasma by mouth and has remained well.

A point that I have always insisted upon is that pus and blood clot must be evacuated. A joint must be aspirated and aspirated again if permanently crippling adhesions are to be avoided; and again, a loose tooth which is oozing must be extracted before the patient becomes anaemic. Plasma by mouth, vitamin K, and plasma applied to the socket on a pad, with the patient biting on it, have always succeeded in stopping the bleeding.

There are other less dramatic cases which I could record did space permit, and some of these have been successfully treated solely by plasma given by mouth. But neither transfusion of blood nor plasma by mouth will have any immediate effect on controlling bleeding coming from the kidney. This is always

troublesome, and takes some time to stop. Again, none of these measures will have more than a slight temporary effect when haemolytic pyogenic organisms are at work in the blood stream. The rule holds here, as elsewhere, that pus in any quantity must be evacuated if blood, plasma, or penicillin is to be effective. Whenever the condition is really dangerous the first measure should be immediate transfusion of plasma followed by properly grouped blood. (We found in the case described above that cross-grouped blood was infinitely more effective than ordinary stored blood.)

Finally, it is not claimed that the use of plasma by mouth is established by the apparent results obtained in a few cases, but since it has seemed to be very helpful, particularly as a prophylactic measure, it is recorded here so that others may assess its value in due course.—I am, etc.,

Bristol.

FREDERICK SUTTON.

Fibrin Foam and Fibrin Films

SIR,—I have read with interest your annotation (Aug. 3, p. 165) on fibrin foam and fibrin films. May I draw your attention to a rather obvious mistake in the reference to sterilization? The writer states: "Fibrin film, in fine transparent sheets sterilized by glycerol or, more conveniently, by heat..." Obviously sterilization in glycerol would not do at all. What is meant by the original workers in this work is: heating in ethylene glycol to 120° C. for at least 10 minutes. The ethylene glycol is a plasticizer; were water the plasticizer or water-soluble plasticizers used in the composition of the plastic fibrin tissue-reaction would be much more marked even if the material survived the treatment. That it does not react kindly at all to any form of heat treatment was found in experiments by Sorsby, Dollar, and myself in 1944 (*Trans. ophthalm. Soc. U.K.*, p. 187), and this has been the case in further work by me.

I also note the omission of reports of further progress—which has been considerable—in this field. I refer in particular to the work at Columbia, Vanderbilt, and Harvard, and at the Mayo Clinic, by Frantz, Light, Pilcher, Meacham, Uihlein, and a few others, describing oxycellulose, the gelatin-sponge, etc.—materials which have undergone considerable clinical trial in the United States. A full bibliography can be found in any of Dr. Frantz's admirable papers—namely, "Oxidized cellulose-absorbable gauze" (1945). *J. Amer. med. Ass.*, 129, 798–801. or "New Absorbable Hemostatic Agents" (1946). *Bull. N.Y. Acad. Med.*, 22, 102–110. Mention of and reference to published work in this new and interesting field of applied surgical research should in my opinion form part of any editorial which is to be regarded as a comprehensive account of achievement in any particular field it deals with.—I am, etc.,

Sutton.

GEORGE BLAINE.

Penicillin Solutions for Injection

SIR,—In suggested methods for the preparation of penicillin solutions for injection "sterile normal saline" figures prominently in many publications. It has recently been adopted as an official recommendation by the *British Pharmacopoeia*. We have been puzzled as to why "normal saline" should be used for intramuscular or subcutaneous injection and we would be interested to learn if this has any specific merits over distilled water, which is the usual diluent for injection purposes. It would seem to add a quite unnecessary complication to penicillin therapy in general practice as "sterile normal saline" is not a very readily available material outside hospitals.

It is obvious that solutions for injection should be as near as possible to the tonicity of plasma and it seems probable that normal saline was recommended on the supposition that this would produce isotonic solutions. However, the tonicity of penicillin solutions depends not only on the presence or absence of sodium chloride but also on the amount of penicillin dissolved in the water and on the amounts of impurities present in the commercial sample apart from the active antibiotic. Commercial penicillin of 500 units per mg. contains less than one-third penicillin, and a solution of this material containing, say, 20,000 units per ml. will contain 40 mg. of the powder per ml. or 4% weight in volume of total solids. With higher potency material of 1,300 units per mg. a solution of 20,000 units per ml. will contain approximately 1.5% weight in volume of solids, and a solution made from the same material to contain 100,000

nits per ml. will have a total solid content of approximately % weight in volume. These examples show how the nature of the solution varies with the purity of the penicillin used and the strength of the solution required.

Our results with red cell haemolysis given in the table below illustrate the tonicity of solutions of penicillin of different strengths and made from penicillin preparations of varying purity. For this work batches of penicillin of low potency, high potency, and pure penicillin were used. Solutions were prepared in sterile distilled water in small tubes and fresh human red cells were added. After 15 minutes at room temperature tubes were examined for haemolysis of the cells.

Batch of Penicillin	Potency u./mg.	Penicillin Units per ml. of Solution				
		50,000	20,000	10,000	5,000	2,000
A "commercial" ..	545	0	0	0	+	++
B " " ..	1,358	0	0	++	++	++
C "pure" ..	1,650	0	++	++	++	++

0 = No haemolysis. + = Partial haemolysis. ++ = Complete haemolysis.

It can be seen from the table that with sample "A" human red cells were partially haemolysed in a solution containing 1,000 units per ml. but not in the more concentrated solutions. Solutions containing 10,000 units per ml. of the higher potency sample "B" were hypotonic, whereas with 20,000 units per ml. no haemolysis occurred. Solutions containing 20,000 units per ml. made from pure penicillin were hypotonic but not those containing 50,000 units per ml. These results can be substantiated by the cryoscopic method. The more concentrated solutions of penicillin are certainly hypertonic, and the addition of sodium chloride would appear to be quite unjustifiable for this would only increase the hypertonicity.

Information at present available does not indicate that sodium chloride has any advantage in maintaining the stability of solutions of penicillin. The recommendation of the *British Pharmacopoeia* that solutions for injection should not be kept for more than seven days at 4°C. is certainly sufficiently cautious.—We are, etc.,

Glaxo Laboratories, Ltd.

Syphilis Masked by Penicillin

SIR,—The possible danger of masking an incubating syphilis during treatment of a recent gonorrhoea by penicillin, first suggested by Scott Cowe and myself (1945) and recently echoed independently (1946) by Allan, Batchelor, Donald, and Murrell, is really part of the wider problem of therapeutic penicillin generally, and I would suggest that the following criteria are essential in any true evaluation, both immediate and remote, of this truly potent preparation.

(1) Penicillin is bacteriostatic and bactericidal to many pathogenic and non-pathogenic organisms. (2) It has no effect on increasing the defensive and reparative processes of the body. (3) It has no effect on "walled-off" lesions, and it is so rapidly excreted that on cessation of treatment its effect quickly falls to zero. Consequently any organisms that escape destruction must be dealt with by the body defences *per se*. (4) Time and dosage factors.—Period of administration and dosage are of necessity empirical, and cure rates approaching 100% in no way absolve us from individual assessment in every case. (5) Instability.—This property bids us be ever on our guard against loss of potency, more especially now that penicillin is generally released from central control. (6) Lastly, a point that often receives scant attention—i.e., that the pathological and reparative processes brought about by disease may by their very nature militate against cure although the causative organism is very susceptible to the drug.

If due consideration is paid to all the above factors many interesting possibilities, sometimes amounting to probabilities, suggest themselves. For instance, apart altogether from masking an incubating syphilis the typical lesion of syphilis itself, especially when modified by time, tends to assume a "walled-off" lesion, and perhaps here we have the explanation of the higher failure rate the later treatment is commenced. Again, on purely pathological grounds in ulcerative endocarditis I would suggest that the result of treatment is to convert phase

(i) characterized pathologically by the "raw" valve and clinically by bacteraemia, emboli, and fever to phase (ii) characterized by the "healed" valve of the well-known asymptomatic stage. Claims of cure therefore must be viewed with a healthy scepticism, and perhaps repeated courses may be necessary to control the disease. From the listed criteria also the disappointing results in dermatology are more easily understood. And finally, in view of the recent recognition of the value of some intestinal bacterial products to the body economy the non-toxicity of penicillin may have to be reconsidered since it is possible that syndromes, perhaps long-delayed and apparently unconnected with the therapy, may occur. The partially successful attempts of oral therapy increase this possibility, and it is interesting to record that in a personal communication Dr. Doayne Bell has encountered a widespread purpura developing after treatment by oral penicillin which responded to vitamin therapy.

Finally, may I digress in order to ask if the subcutaneous implantation of solid penicillin has been tried as a means of prolonging its action as this method has been so highly successful in the use of other preparations?—I am, etc.,

The Pathogenesis of Cancer

SIR,—I was interested to read in the *Journal* of Feb. 16 (p. 242) the annotation headed "Testosterone Prophylaxis of Mammary Cancer" and in particular this sentence: "A major outcome of cancer research in recent years has been the recognition that many tumour types are closely dependent upon specific hormonal changes for their inception and, in some cases at least, for their subsequent growth." I would like to offer the following observations.

Being unable personally to undertake researches which would be costly and prohibitive to the general medical practitioner, I wished to stimulate investigations in cancer on the crux of the problem, the solution of which is of such far-reaching importance to the world in general. After the termination of my studies for entry into the medical profession at Madrid I published an article "A Hypothesis on the Pathogeny of Cancer" in the review *El Siglo Médico* (1927, No. 3857, p. 467) in which I suggested the following: (1) Cancer is a neoformation made up of epithelial cells which regain their embryonal karyokinesis owing to the absence or weakness of the endogenous stimulus which would restrain commonly cellular mitosis. (2) This stimulus is represented by some of the sexual hormones. (3) Despite the control or check which prevents the excessive multiplication of the cells these retain their tendency to divide and in fact are relatively autonomous, and it is indispensable to assist organic necessities.

Many years since I have had the satisfaction of confirming that the researches on the cancer problem are proceeding on the lines we indicated in 1927, and I am glad that my theory has been a small contribution to cancer research, though I am far from suggesting that it would have solved a problem of such immensity.—I am, etc.,

Africans, Peptic Ulcers, and Parasyphilis

SIR.—If Abdulla read the *B.M.J.* he would be hurt by Sir Heneage Ogilvie's comment (May 25, p. 800) that Africans seem to be immune to peptic ulceration. For Abdulla is an old Nubian, who blew the bugle for Kitchener at Omdurman and, domiciled in Kenya, suffered from abdominal pain and repeated haematemeses, until in 1941 Sir Heneage (then Col.) Ogilvie performed a partial gastrectomy for a gastric ulcer which had penetrated to the pancreas. The result has been excellent and the writer, as the mere go-between, receives periodic presents of eggs from a grateful patient. Acute and chronic progressive peptic ulcerations, with haemorrhage and perforation as complications, do occur in East Africans, probably less commonly than amongst Europeans, and perhaps with a greater incidence amongst the urban African than

the others. Perhaps Sir Heneage Ogilvie does not mean us to take him literally, but I fear that we must be blamed for having failed to wrest him from our surgical colleagues—how else can we explain his comment (*Lancet*, 1945, 2, 586) that the African "contracts syphilis, but it never goes on to parasyphilis"? Meningovascular syphilis, epileptiform attacks from cerebral syphilis, and general paralysis of the insane are far from uncommon, although tabes dorsalis is, apparently, peculiarly rare.

If we have given any false impressions to our visitors, we apologize; for, if Sir Heneage Ogilvie found the officers of the East African Medical Service helpful, we greatly appreciated the visits of the surgeons and physicians, who lightened our darkness and enriched our B.M.A. meetings.—I am, etc.,

FREDK. J. WRIGHT, M.R.C.P.,

Menstrual Changes in Hot Climates

SIR,—Dr. W. P. Grieve (Aug. 17, p. 243) asks if any investigation was made of menstrual variations among auxiliaries serving in hot climates. In 1944 I obtained menstrual histories at medical inspections or special interviews from 500 British Service women of whom 42 were Q.A.I.M.N.S. and 458 A.T.S., and whose service in the Middle East ranged from six months to two years.

Menstrual changes, chiefly menorrhagia, were common, but amenorrhoea was not at all a prominent condition. Only 11 had suffered from amenorrhoea on arrival for a time ranging from six weeks to five months, whereas 32 had previously experienced amenorrhoea of from two months to two years, either between the ages of 16 and 20 on starting nursing (15 out of 42 nurses) or on joining the A.T.S. Six of these 32 had again had amenorrhoea on arrival in the Middle East and are included in the 11 mentioned above.

It would seem therefore that a change to a hotter climate is not in itself a prominent cause of amenorrhoea.—I am, etc.,

London, S.W.7.

MARGARET E. R. BALFOUR.

Foreign Body in the Gut

SIR,—I enclose an account of a case that came into my hands more than a quarter of a century ago. There are several features of interest:

Female patient. Complained of chronic diarrhoea for last two years. *Previous history*.—Hysterectomy two years previously. Felt well for ten days after operation, when sudden attack of diarrhoea occurred. *Examination*.—Patient pale, thin, looked ill. Tumour felt in right iliac fossa. Carcinoma of caecum suspected. Barium enema shows normal caecum. *Operation*.—Incision right iliac fossa. Caecum and appendix normal. Hard mass felt within small gut about one foot above ileo-caecal valve. It was found impossible to move the mass either way within the lumen of the gut, so the top was isolated, the mass removed, and the incision in the gut wall closed. The patient made an uninterrupted recovery, and the diarrhoea ceased almost immediately.

The mass was about the size of a cricket ball and proved to be a complete coiled-up strip of gauze. Presumably it had gravitated to the upper abdomen while the patient was in the Trendelenburg position during the hysterectomy, been inadvertently left in, and become shut off between the transverse colon and the jejunum. Spontaneous junction had followed and the gauze had slipped into the jejunal lumen.

I am, etc.,

St. Leonards-on-Sea.

D. LIGAT.

Demobilized Service Medical Officers

SIR,—On a recent trip I have had an opportunity of seeing a number of ex-Service medical officers, and it has been something of a shock to realize the strong feeling which prevails among them about their treatment by the Service. It is alleged very bitterly that men who have been doing specialist work, although they were "given to understand" or as some say "promised" that after demobilization they would be given the benefit of further training in their specialty, have been "fobbed off" with a short refresher course. Who is responsible for what they regard as a gross breach of faith I am not in a

position to say. It has even been suggested that it is part of a subtle plan to cause disgruntlement, dissatisfaction; and even pressing need—as it was put to me: "to throw us into Bevar arms to work his National Health Service from sheer necessity to earn bread and butter."

It seems to me that the time has come to appoint a B.M.A. ex-Serviceman's Committee composed of ex-Service medical officers, with a chairman who would be an *ex-officio* member of Council, to deal with the acute problems of a very large number of our profession whose lot in many cases could be described not unreasonably as nearing desperation.—I am, etc.,

H. M. STANLEY TURNER,

Wing-Comdr., R.A.F. (retd.).

Brookwood.

The London College of Osteopathy

SIR,—As the Dean of the above college it is my duty to reply to the letter from Mr. W. E. Tucker (July 27, p. 141). Whatever the orthopaedic surgeons or the physiotherapists know of manipulation has been gleaned from the osteopaths. Twenty-five years ago an article in a leading British medical journal stated it was impossible to move by manipulation any joint of the spine. This was the generally accepted view of the medical profession. If it had not been for the osteopaths the progress of manipulation within the orthodox profession, if adequate as it even now is, would have been exactly nil.

Within the last ten years neurological and orthopaedic surgeons have "discovered" that many cases of sciatica are due to pressure, probably from intervertebral disks, on the roots of certain nerves. Forty years previously osteopaths had pointed out that frequently sciatica was due to pressure on nerves from mechanically deranged tissues of the lumbar region, including the intervertebral disks. The interesting and illuminating surgical advances that are being carried out in connexion with the intervertebral disk have already gone far to establishing the osteopathic lesion as an aetiological entity. The development of a proper assessment of the osteopathic lesion is still, however, in its infancy, and while many mis-statements have been and still continue to be made about it there is no shadow of doubt about its existence. As the Minister of Health recently pointed out, the heterodoxy of yesterday frequently becomes the orthodoxy of to-day, and the medical profession to-day practise many forms of therapy which it yesterday rejected.

The basic principles that are to be taught at the above college have been circulated to all educational bodies in this country and they are not erroneous. We are confining our students to registered medical practitioners so that the osteopathy of the future will be adequately trained in the basic principles of medicine and will have educationally conformed with the requirements of the authorities of the land.

There is no ulterior motive behind the action of the British Osteopathic Association such as Mr. Tucker suggests. The sole object is to promulgate the principles and technique of osteopathy and to prevent the exploitation and overlaying of the art of manipulation by any sectional interests such as he represents.

The British Osteopathic Association is not asking for any recognition from the medical profession or any other body. If British medical practitioners do not care to avail themselves of this opportunity there is an end to the matter, but any organized boycotting of this unselfish and laudable effort of the British Osteopathic Association will necessarily play into the hands of the inadequately trained osteopath whom the Select Committee of the House of Lords rightly exposed.—I am, etc.,

London, W.1.

GEORGE MACDONALD.

Osteopathy

SIR,—Mr. W. E. Tucker (July 27, p. 141) refers to the basic principles of osteopathy as erroneous. In any curative method conceptions about its basic principles—from advocates or opponents—are less important than good results. It has even happened in the past that the one has had to be adjusted to meet the demands of the other. As regards osteopathy in its actual clinical results, I do not believe this has ever been fairly investigated by our profession.—I am, etc.,

New Malden.

S. RANSOM.

Unsigned Reviews

SIR,—I heartily endorse Mr. H. Osmond Clarke's views on anonymous reviews (July 20, p. 102). Why should a signed author be "potted at" by an unsigned reviewer? In a review of *A Descriptive Atlas of Radiographs* it was stated that the plates were placed haphazard when it was one of the key features that the normals were arranged on the left- and the abnormal on the right-hand pages so as to be readily compared with one another. Protest brought no satisfaction. I once had the good luck of recognizing one reviewer by a certain cheapness which characterizes his writings. I have approached several editors, but they merely state that the good name of their respective journals was sufficient safeguard against wrong judgment. Let us at least have initials.—I am, etc.,

London, W.1.

A. P. BERTVISTLE.

Protection against Sexual Offences

SIR,—Dr. Clifford Allen, in his letter (July 27, p. 136) criticizing the efficacy of short-term imprisonment in preventing the repetition of sexual offences, asserts that "the only solution to this problem would be to give the prisoner a life sentence or else to regard the behaviour as an illness and treat it."

I would agree with his alternatives had his last phrase read "and cure it," for is it a solution for an unsuccessfully treated perversity to be released, again to debauch children and maybe to commit murderous assaults upon women?

He asserts that few cases receive treatment in prison, but can he assure us that treatment by a psychiatrist would produce the high percentage of cures that would be necessary to allay the fears of those who would go to any length to protect women and children from outrage?

As a general practitioner with no experience of the technique of psycho-therapy, my psychopaths and neurotics return to me after periods of treatment by psychiatrists, and few appear to have received benefit from their treatment. Can one expect any better results from the treatment of those sentenced for sexual offences? One can, however, put forward a proposal which would, I think, solve this problem. By the obligatory castration at the commencement of his sentence of every person convicted of a sexual offence against a woman or child, one could assume that, at the end of his incarceration, impotence and loss of desire would render him incapable of harm, and during the period of his imprisonment such treatment as may be considered desirable could be rendered without any misgivings on the part of the psychiatrist as to the effect upon some innocent third party of a failure of treatment.—I am, etc.,

London, N.15.

L. B. LIEBSTER.

The Epidemiology of Infectious Diseases

SIR,—With reference to my letter (June 8, p. 887), I beg to suggest that the clue to the mystery of the mechanism by which infection in influenza and other epidemic diseases survives through long interepidemic periods is to be found in the instability of the molecular structure of viruses. Fenton (1945) writes:

"[Viruses] are giant molecules containing hundreds of thousands of atoms that are linked in complex groups and series. For generations these molecules may remain stable. Then they abruptly change. Thus the virus which normally causes tobacco mosaic may add a few thousand atoms and become a variety that produces the much more virulent disease known as acuba. Other modifications may cause a disease that kills the affected plant [outright] or make the virus so weak that its effects can barely be detected. Apparently a single virus strain may appear in any or all of these forms, shifting from one to another as atoms are gained or lost."

An analogous mechanism in bacteria also may not unreasonably be inferred. The variations in virulence which commonly occur in epidemic diseases are well illustrated by the history of scarlet fever. According to Singer (1928) scarlet fever first became clearly recognizable as a mild disease without prominent symptoms about 1650. Good observers in the half century which followed considered it a new disease. In England it continued to be of little importance till about 1748, when it began to be associated with grave throat symptoms. This phase continued for about ten years. The virulence then dropped, and the disease continued of slight importance till 1785. It then grew virulent again and remained so until about 1808. The

malignancy then fell and remained low for about thirty years. It rose again about 1837, and from then till 1894 it was one of the great killing diseases, especially of children. Since then the mortality from it has steadily decreased.—I am, etc.,

The Burden of the M.R.C.P.

SIR,—Whatever may be the case in the future, many of the people who have taken the M.R.C.P. did so in order to enter consulting practice, of course hoping that the day would come when they would be elected to the Fellowship. But what did not strike them was that if that day did not dawn the M.R.C.P. would be worse than useless because as the years go by and the man remains a member some of the doctors who have been in the habit of referring patients to him begin to think that his abilities are after all less than they thought. If he had ever taken the membership but had his M.D. the idea that the absence of the fellowship was a stigma would never have struck them.

The disability under which the M.R.C.P. of many years' standing labours is the greater because he is probably not on the staff of a teaching hospital; a lack which makes his path as a consultant more difficult. Of course the member of a teaching hospital staff is more likely to get the fellowship, mainly because his senior colleagues are likely to propose him, whereas nobody is likely to be so directly interested in the non-teaching consultant.

Would it not be more equitable if after the lapse of not less than five years after taking the M.R.C.P. the member might submit his name together with such evidence of professional attainments (excluding testimonials and the names of referees) as he thinks might convince the College that he is a fit and proper person for election to the Fellowship?—I am, etc.,

DUM SPIRO SPERO.

Notification of Venereal Disease

SIR,—In his letter advocating compulsory treatment, Dr. G. G. Thyne (Aug. 3, p. 175) states: "It would be a very strange man, whether he was a venerable dean or bus conductor, who has not at some time or other run the risks of venereal infection." This statement requires challenging. It is based on the old heresy, unfortunately still implied in some health lectures, that to refrain from promiscuity is unnatural, abnormal, or even detrimental to health. This heresy is not only contrary to considered medical opinion but is disturbing to parents and youth leaders and entirely opposed to the ideals of pre-Service units, whose charges are entering the Services daily. Furthermore it is deeply resented by a large body of men (and women) who, conscious of natural desires to satisfy a normal sex urge, not only prefer to wait for that complete satisfaction they look forward to experiencing in the permanent companionship of a future marriage with its harmonious union on all levels, but intelligently refuse to spoil its resultant happiness by either the possible risks of V.D. or the sordid memories so often associated with the doubtful pleasures of the temporary liaison of promiscuous living. As it also encourages men of poor moral sense, and causes others, who but for the dislike of being thought unnatural, etc., would not otherwise do so, to expose themselves to infection, the continued propagation of this heresy is detrimental to the efforts being made for the prevention and control of V.D.

There is a vital need to-day for men (and women) to understand that even if the risks of V.D. and pregnancy could be completely eliminated there still remain the results of the promiscuous act itself. These are not only the psychological disharmony arising out of inner conflict and leading on to disintegration of the personality and a loss of self-respect, but also (and this is important) a serious undermining of those qualities of love, loyalty, and responsibility essential to successful, stable, and permanent marriage, resulting in a serious collapse of home and family life. This not only causes severe mental strain and physical ill-health to the parties concerned, but robs children of that love and sense of security essential to their moral and physical health.

The only measure giving complete protection is "self-control." This is neither easy to advise or carry out. But where, in addition to advice necessary to protect the wilfully promiscuous, the preventive of self-control is presented in terms of "consideration for others" men will respond grandly to an appeal to face up to this duty which is embodied in the common ethic of Christianity and sportsmanship. These facts are borne out by an experience of Service life (recruit to combatant officer, home and abroad, in peace and on active service) and youth- and marriage-guidance work.

In closing, and for the encouragement of those called for duty in the Services, some twenty years of lecturing on the above lines to recruits (men and boys) of the three Services show that such information, far from being resented, is sincerely appreciated. The outstanding question, "Why are we not given this information by parents, schools, etc., earlier?" or "now, by our own M.O.s?" is a challenge not only to those responsible for the health and leadership of young men and women, but to those bodies responsible for their training.—I am, etc.,

Bristol.

WILFRID WAGLAND.

Post-haemorrhagic Blindness

SIR.—Recent communications in the *Journal* prompt me to put yet another case of post-haemorrhagic blindness on record. The patient (a fisherman aged 54) was admitted to hospital in an extremely weak and collapsed state as a result of recurrent melaena over a period of four days previously. At the time of admission haemoglobin estimation was 30% (Haldane), plasma CO_2 78 vols. per cent, and the blood urea 40 mg. per 100 ml. The patient was transfused with two pints of Group O blood and on the following morning awoke to find that he was partially blind in the left eye.

Ophthalmological examination revealed a normal right visual field, but the left was contracted to a horizontally disposed band nasally and upwards, including the macular area. The left disk appeared to be definitely pale and there was no evidence of swelling.

Subsequent progress was uneventful: the anaemia responded to the exhibition of iron, with a gradual improvement in the patient's condition. Test-meal showed a hyperchlorhydria with blood in several specimens, and barium-meal examination indirect evidence of ulceration of the first part of the duodenum. Occult blood was present in the stools for some days before becoming persistently negative. Vision in the left eye, after slow improvement initially, has recovered considerably over a period of sixteen months despite the complete optic atrophy, which is now evident.

The unilateral visual loss is not as common as bilateral defects, but of course both are rare complications of haemorrhage.—I am, etc.,

Aberdeen.

WILLIAM R. GAULD.

Sir Frank Colyer Fund

SIR.—I would like to quote the old proverb, "Whatsoever thy hand findeth to do—do it with all thy might," for in suchwise Sir Frank Colyer has ordained his life should be lived, and the dental profession has reaped in full measure the harvest of his strenuous labours. The writer had the privilege of seeing their commencement when sixty long years ago Sir Frank was assistant house-surgeon at the Royal Dental Hospital; and many old students there must be who in later years knew him, and remember him as teacher and Dean. His pen too has enriched clinical and scientific dental literature, while for over thirty years he has been curator of the museum of the Odontological section of the Royal Society of Medicine. So successful has been its growth and development that it is now amalgamated with the Hunterian Collection in the Royal College of Surgeons museum.

As a mark of appreciation for his sixty years of tireless and high endeavour it is proposed to make a gift to him of his portrait on September 25—his 80th birthday—a gift not from any learned society but from the rank and file of the dental profession. As one of them I appeal to all and sundry to contribute generously to that gift. Contributions should be addressed to: Mrs. Thurston, "Brentknoll," Radlett, Herts, and envelopes marked "Sir Frank Colyer Fund." Any surplus after paying for the portrait will be used as a fund for the further development of the Odontological Museum.—I am, etc.,

Nottingham.

F. C. PORTER.

Obituary

OTTO MAY, M.A., M.D., F.R.C.P.

The sudden death of Dr. Otto May deprives the community and the medical profession of a singularly able and attractive personality, and will make a deep breach in the many circles of friends where his presence was always a refreshment and a delight.

Otto May was born in 1879, educated privately and at St. John's College, Cambridge, where he took a first in both parts of the Natural Sciences Tripos. Remaining in Cambridge he became a demonstrator in physiology and a most successful coach. He also made a real attempt to enter research, and the instance of Prof. Langley undertook a study of the mechanism of pancreatic secretion that is excited by the entry of acid into the duodenum. It so chanced that Bayliss and Starling were also engaged upon this research problem, and the discovery of secretin, and the general conception of hormones that arose from it, solved the question to which May was independently, seeking the answer. He thereupon came down and entered University College Hospital to take his medical degree. He was one of a small number of brilliant young men who entered the hospital from Cambridge at about that period and lent to the student body of their time an animation and distinction that the present writer, who was their junior, still retains as one of his happiest recollections.

His hospital career was highly successful. He took the Atchison Scholarship and the Liston medal and, upon qualification, a British Medical Association research scholarship. He was later one of the first group of Beit Memorial Fellows, a group which included the late Sir Thomas Lewis and Sir Edward Mellanby. For a time he worked in the laboratory of Sir Victor Horsley, and some original papers in *Brain* mark this period of his life. Turning then to clinical medicine he showed the same easy brilliance of which his earlier activities had given earnest, and would in time have doubtless made a mark for himself in consulting medicine, but shortly after becoming physician to the Evelina Hospital for Children he made his last change and entered what was to be his life's work, the field of insurance medicine. As principal medical officer to the Prudential Assurance Company he quickly made his mark in this field of medicine, in which he became a recognized authority, revivifying it and bringing it into touch with the advance of medicine. His contributions to the transactions of the Assurance Medical Society were of outstanding merit and gained for him the unusual distinction of honorary membership of the Association of Life Assurance Directors of America. Outside this work his deepest and most abiding professional interest centred round the problems of venereal disease, a subject to the elucidation of which he wrote a number of forceful, clear, and valuable papers in various journals. At the time of his death he was chairman of the British Social Hygiene Council; and he will be deeply missed by his fellow workers on this body.

Otto May was a fervently loyal son of his old hospital, and his memory is perpetuated there by the *U.C.H. Magazine*, of which he was one of the founders and the first editor. But it is not wholly or mainly of these fruitful achievements that those who had the delight and privilege of his friendship will now be thinking. Otto May was far more than the work he did. His friends will recall his perennially youthful spirit, which the passing years seemed not to have touched, his singularly attractive smile and his whimsical humour, his modesty, those warm family feelings that made his home so pleasant a haven, his live interest in the humanities, and his complete integrity. The sympathy of all his friends will go out to his wife and to his two sons in their loss.

Dr. T. W. PRESTON writes: I first became associated with Otto May in 1927 and worked with him at the Prudential Assurance Company until he retired in 1938. As an authority on assurance medicine he had a reputation which extended to all parts of the world where life assurance is conducted. He had an alert brain and considerable clinical acumen, although it was many years since he gave up clinical medicine; there is no doubt that had he chosen another path he would have attained a reputation as a consulting physician. May chose to pose as something of a cynic; but this was a thin veneer which deceived nobody. His friends mourn a loved and warm-hearted colleague.

PENICILLIN LOZENGES

Troch, Penicil., B.P.

EACH lozenge contains 500 international units of penicillin (calcium salt). They provide a convenient means of maintaining an effective degree of antibacterial activity in the saliva throughout the day.

Penicillin lozenges are especially indicated in the treatment of Vincent's angina, acute tonsillitis, fusospirochaetal gingivostomatitis and also streptococcal carriers.

Her many friends were shocked to learn of the sudden death of Dr. ELEANOR CICELY THISTLETHWAITE. She was born in the Philippines in 1896, and after graduating M.B., Ch.B. at St. Andrew's, held resident posts at the Queen's Hospital for Children, Hackney. Between 1926 and 1931 she was in general practice in the Gray's Inn Road and Camden Town, and then held various temporary posts, including one at the London Lock Hospital. In 1935 she became visiting medical officer to St. Margaret's Hospital, Kentish Town, where she was responsible for the care of children suffering from vulvo-vaginitis and ophthalmia neonatorum. She carried on this work until the outbreak of war, when she was appointed medical officer to a mobile Naval train, and rendered valuable service during the evacuation of the wounded after Dunkirk. Subsequently she was appointed assistant medical officer of health, St. Pancras, with special responsibilities in connexion with air raid precautions, and served all through the first London bombardments, often staying at the first-aid stations both by night and by day. The late Maitland Radford formed a very high opinion of her conduct and services throughout this testing time, and commended her most warmly to the writer. At the beginning of 1943 she was appointed assistant medical officer, County Borough of Southend-on-Sea, and did valuable work, both in the school medical service and the V.D. treatment centre. She gained the confidence of patients, parents, and children; her kindly personal interest and wide experience of life quickly enabled her to make a unique position for herself, and her sudden and untimely passing leaves a gap which will not easily be filled.

Dr. COLIN MACPHAIL FORBES died suddenly at Weymouth on August 13 at the age of 48. He was born at Ayr and educated at Ayr Academy and Glasgow University, graduating M.B., Ch.B. in 1921. He practised in Weymouth for the major part of his career and was honorary surgeon to the Weymouth and District Hospital. He was a member of the B.M.A. from the time he qualified. Dr. Forbes was a man of many interests and activities, and the crowded church at his funeral service testified to the esteem and affection with which the townspeople of Weymouth held him. He was a surgeon sub-lieutenant in the 1914-18 war and performed his first operation in amputating his captain's finger in an open lifeboat after his ship had been sunk. He was a keen musician and fine pianist. In 1939 he was admitted as a Serving Brother of the Order of St. John and acted as County Commissioner for Dorset in the Brigade. Forbes was called up in 1939 with the Territorials and served throughout the war in the rank of lieutenant-colonel. He had a dry sense of humour and his after-dinner speeches were a delight to all who heard him. "Forby," as he was affectionately called by colleagues and friends, will be sadly missed. —E. P.

BERTRAM SYDNEY NISSÉ, M.D., M.R.C.P., who died on Aug. 14 at Teignmouth Road, Brondesbury, N.W., had made his mark in physical medicine and was a vice-president and former secretary of that Section of the Royal Society of Medicine. Born in 1898 he was educated at St. Olave's School and the London Hospital, where he won the Buxton scholarship in arts. He qualified in 1921, took the M.B. and B.S. degrees of the University of London in the following year, and won the university gold medal in medicine at the M.D. examination in 1924. After holding various junior posts at the London Hospital and at the West End Hospital for Nervous Diseases he became resident medical officer and then chief assistant and medical registrar at the National Hospital for Diseases of the Heart; later he was elected physician to the British Red Cross Society's Clinic for Rheumatism in Regent's Park, when it was established in 1930. Dr. Nissé published a number of papers dealing mainly with cardiology and rheumatism in medical journals and in the *Annals of Eugenics*; he also wrote a small book *Rheumatism* published in 1938. He was a Fellow of the Medical Society of London and the Hunterian Society, and the International Society of Medical Hydrology made him a member. During the war years, while Dr. W. S. C. Copeman was on service in the R.A.M.C., Dr. Nissé took charge of the rheumatism clinic at the West London Hospital. His early death is a loss to the campaign against rheumatism in this country.

We regret to learn of the death in Edinburgh recently of Dr. HUGH FERGUSON WATSON who, for over 14 years, was Medical Deputy Commissioner of the General Board of Control. Before taking up medicine Dr. Watson had been in business for several years. He first qualified as L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas. in 1907, then graduated as M.B., Ch.B.Glas. in 1911. He became assistant medical officer at Glasgow District Mental Hospital, Woodilee, and collaborated

with Prof. Carl Browning and Dr. Ivy McKenzie in research on the Wassermann reaction in syphilis. He made this subject his thesis when, in 1913, he was awarded the degree of M.D. with honours. In August, 1913, he was appointed medical officer at H.M. Prison, Peterhead, and eight months later became M.O. at Perth prison and medical superintendent of the Criminal Lunatic Department. In 1916 he gained the degree of Ph.D.Ed. In October, 1919, he was appointed Deputy Medical Commissioner of the General Board of Control, an office he held till he retired in March, 1934. In 1928 he became a Fellow of the Royal Society of Physicians and Surgeons of Glasgow, and three years later a Member of the Royal College of Physicians of London. On the outbreak of war Dr. Watson's services were enlisted in a team of voluntary members of the E.M.S. prepared to cope with any development of neurosis in the civilian population. Of a retiring and studious disposition. Dr. Watson was held in high esteem by his colleagues who were favoured by his friendship, and these mourn the passing of one whose knowledge of men and motives was wide and well-founded, whose opinion was valued, and who did much good unostentatiously. —J. H. M.

The Services

The Legion of Merit, Degree of Officer, has been conferred upon Major-Gen. Sir Edward Phillips, K.B.E., C.B., D.S.O., M.C., late R.A.M.C., and the Bronze Star Medal upon Col. (Temp.) T. Parr, and Major C. C. Misener, R.C.A.M.C., by the President of the United States of America, in recognition of distinguished services in the cause of the Allies.

The following have been mentioned in dispatches in recognition of gallant and distinguished services in the Far East: Capt. D. L. Broadhead and D. H. K. Soltau, R.A.M.C., Lieut.-Col. (Temp.) S. L. Rikhye, and Capt. B. B. Chetrie and Lal Chand, I.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Died from injuries received in car accident.—Flying Officer William Caldwell Adam, R.A.F.V.R.

Universities and Colleges

UNIVERSITY OF OXFORD

The Theodore Williams Scholarship in Human Anatomy, 1946, has been awarded to M. J. V. Bull, University College. (Proxime accessit: R. G. Willison, Trinity College.)

UNIVERSITY OF CAMBRIDGE

H. Hynes, M.D., of St. John's College, has been appointed Reader in Medicine from Oct. 1, 1946. C. L. G. Pratt, M.D. Liverp., has been appointed University Lecturer in Mammalian Physiology from Oct. 1, and G. P. McCullagh, of Queen's College, University Lecturer in Pathology for three years from Oct. 1. H. Butler, M.B., B.Chir., of Queen's College, has been appointed temporary University Demonstrator in Anatomy.

UNIVERSITY OF LONDON

The prize distribution and a conversazione will be held at the Royal Dental Hospital of London, School of Dental Surgery, 32, Leicester Square, W.C., on Saturday, Oct. 5, at 3 p.m., when the Minister of Health, the Rt. Hon. Aneurin Bevan, M.P., will present the prizes.

Medical News

The work carried out by the Save the Children Fund at Lübeck deeply impressed Sir Hugh S. Robertson on his recent visit to Germany with the Glasgow Orpheus Choir. The choir has sent a gift of £100 to the Fund. In Yugoslavia a group of mothers have expressed their gratitude to the fund workers at Kamenica, and in Greece a relief worker of the fund, Miss A. Forster, has been presented with the Freedom of the City of Xanthi.

Sir John Boyd Orr, Director-General of the Food and Agriculture Organization of the United Nations, hopes that a successor to his post may be found after the autumn conference at Copenhagen. He had previously made it clear that his was a temporary appointment; and his intention is to return to Parliamentary duties as soon as he is released.

The International Anaesthesia Research Society and the International College of Anaesthetists have issued a preliminary programme for the twenty-first Congress of Anaesthetists, which will be held at New York City on Sept. 9-13, 1946. Discussions on all branches of anaesthesia have been arranged, including reports of clinical trials of a new anaesthetic, "metopryl." On Sept. 12 Dr. T. Cecil Gray, of Liverpool, will read a paper entitled "The Use of d-Tubocurarine Chloride in Thoracic and Abdominal Anaesthesia."

Mr. W. McAdam Eccles, M.S., F.R.C.S., consulting surgeon to, and governor of, St. Bartholomew's Hospital, who died on May 30, aged 79 years, left £5,740 15s. 4d. gross, with net personalty £4,367 3s. 6d. Specific bequests included his surgical instruments and appliances to the Regions Beyond Missionary Union; his medical and surgical books to the council of the West London Medico-Chirurgical Society; and his caricatures of past members of the medical staff of St. Bartholomew's Hospital to the governors of the Hospital. The residue of his property he left to his sons Philip Campbell Eccles and David McAdam Eccles, M.P.

EPIDEMIOLOGICAL NOTES

Typhoid Epidemic

Notifications from the Aberystwyth epidemic reached a total of 135 by Aug. 27, and there have been 4 deaths. It is not expected that there will be many more cases in the town itself.

Cases of typhoid infected at Aberystwyth are still being reported from other areas. Within the last week Northampton has had 5 cases, all returned holiday-makers, Oldbury 4, Banbury 2, Keighley 1, and Stafford 1.

Ice-cream Again

An outbreak of food-poisoning has occurred in Boston, Lincolnshire. Ice-cream from one source, prepared by the cold mix process, was consumed by the 70 cases investigated. *Salmonella typhimurium* has been isolated from the stools of notified cases but not from the ingredients of the ice-cream.

At Coatbridge, Lanarkshire, 36 people are under observation after eating ice-cream prepared by a man believed to be a typhoid carrier.

Discussion of Table

In England and Wales there were decreases in the notifications of scarlet fever 233, measles 241, whooping-cough 182, and pneumonia 58. An increased incidence was reported for typhoid 29, and dysentery 25.

A fall in the notifications of scarlet fever was reported in most areas of the country, and notably in Staffordshire 49. The largest decreases in the incidence of whooping-cough were London 38 and Warwickshire 33.

There were fewer cases of measles in Middlesex 106 and Surrey 69, and more notifications in Durham 60, Lancashire 38, and Warwickshire 31. Cases of diphtheria fell by 3 below last week's record low level; the largest of the local variations were an increase of 12 in London and a decrease of 11 in Staffordshire. The largest returns of dysentery were those of Lancashire 15, Kent 13, and London 12.

In Scotland there were decreases in the notifications of acute primary pneumonia 33 and scarlet fever 16. A decrease of 7 in cases of dysentery gave the lowest return for recent months.

In Eire the large increase of 99 in cases of whooping-cough was mainly due to an outbreak involving 88 persons in an institution in the rural district of Dublin North. The rise in the incidence of diarrhoea and enteritis was due to 38 cases notified from an institution in Dublin C.B. in respect of previous weeks.

Quarterly Return for Eire

During the March quarter a birth rate of 22.5 per 1,000 was recorded, which was 0.9 above the rate for the first quarter of 1945. Infant mortality was 81 per 1,000 births and was 8 and 20, respectively, below the rates for the two previous March quarters. The general death rate was 17.4 per 1,000, being 1.1 below the 1945 figure. Altogether 239 deaths were attributed to diarrhoea and enteritis under 2 years; this was 28 above the average for the five preceding first quarters. Deaths from pulmonary tuberculosis numbered 677 and from other forms 197, figures which were 183 and 39 below the averages of the five preceding March quarters. There were 46 deaths attributed to diphtheria and 34 to whooping-cough.

Week Ending August 17

The notifications of infectious diseases in England and Wales during the week included, scarlet fever 690, whooping-cough 2,097, diphtheria 251, measles 2,712, acute pneumonia 300, cerebrospinal fever 47, acute poliomyelitis 33, dysentery 70, paratyphoid 60, typhoid 53.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Hydroorrhoea Gravidarum

Q.—*What causes spontaneous leakage of liquor amnii between the twentieth and thirtieth weeks of pregnancy? What are the prospects of foetal survival? Can the present apparent prevalence of the condition be explained?*

A.—Leakage of liquor amnii implies rupture of the membranes, and when it occurs during pregnancy is to be regarded as accidental, although it might be associated with an inherent weakness of the membranes or lack of cervical support due to a previous laceration or high amputation. There is no evidence to suggest that this accident is more frequent now than formerly.

When the membranes rupture during pregnancy the outlook for the foetus is poor, because abortion or premature labour nearly always occurs within a few days. However there are cases recorded in which the pregnancy has continued for as long as 50 to 120 days afterwards and the child has survived. One possibility is for the membranes to rupture and then retract from around the foetus, which thereafter develops outside them (*grossesse extramembraneuse*). This is accompanied by a continuous or intermittent discharge of liquor during the pregnancy and the child rarely survives, since it tends to be born prematurely and in any case is feeble and often deformed.

Another possibility is that the fluid discharged is not liquor amnii but an unusually heavy secretion of the uterine glands which tracks down between the decidua vera and the decidua capsularis. This condition is rare and is supposed to be associated with some type of decidual endometritis. Its pathology is extremely doubtful, and it is possible that all cases described as such have in fact been examples of *grossesse extramembraneuse*. In any case abortion and premature labour are again common although not inevitable. The continued discharge of fluid from the uterus during pregnancy—liquor or otherwise—is usually called hydroorrhoea gravidarum.

Finally, the possibility that the fluid is urine, the patient suffering some lack of control over the bladder, should not be overlooked.

Penicillin for Pregnant Syphilitic

Q.—*A patient with syphilis contracted five months ago became pregnant at the time of infection. Treatment with N.A.B. and bismuth was begun at the 14th week, since when a total of 1.9 g. of N.A.B. and 1.5 g. of bismuth has been given. As I am anxious to combine penicillin with routine arsenical therapy please suggest total dosage and duration of penicillin treatment. Admission to hospital for three-hourly injections is impossible.*

A.—The aim should be to administer 4,200,000 Oxford units of penicillin; these may be given in doses of 300,000 units intramuscularly once or twice daily, and the period of treatment will therefore be 7 or 14 days. Arsenic and bismuth should be continued at least to the termination of pregnancy, and a course of treatment should be prescribed during any subsequent pregnancy. It has been suggested that penicillin may tend to cause abortion, but the consensus is against this; nevertheless the possibility should be kept in mind. Admission to hospital is unnecessary for the penicillin injections.

Nicotine and Nicotinic Acid

Q.—*Is there any chemical and/or pharmacological similarity between nicotine and nicotinic acid? Why have the Americans given the name niacin to nicotinic acid?*

A.—Nicotine and nicotinic acid have some chemical similarity inasmuch as both are derivatives of pyridine. Nicotine is a combination of pyridine with methylpyrrolidine. Nicotinic acid is pyridine with a COOH group attached at the same point as the methylpyrrolidine is attached in nicotine. There is no pharmacological similarity between nicotine and nicotinic acid. "Niacin" has been chosen by the compilers of *New and Non-official Remedies* as a name in which there are no proprietary rights. It is partly made up of the first two letters of each of the two words "nicotinic acid." The word "niacin" seems scarcely necessary, and was apparently introduced because of the possible association in the lay mind of nicotinic acid with the poisonous substance nicotine.

Treatment by Fibrolysin

Q.—*Please give an account of treatment with fibrolysin of Dupuytren's contracture of the palmar fascia.*

A.—Treatment of Dupuytren's contracture by injections of fibrolysin has not proved satisfactory. Fibrolysin is a preparation containing sodium salicylate and allyl thiourea; when administered hypodermically it is supposed to have a softening or solvent effect on scar tissue. A solution of 10 parts of the drug, 20 of glycerin, and 70 of water is suitable. The dose is from 0.5 ml. up to 3 or 4 ml. of the solution given hypodermically at intervals of a few days. Experience has not confirmed the claims at first made for it.

Bite by Dog with Tetanus

Q.—*A man was bitten by a tetanic dog. I gave him 3,000 units of A.T.S. and repeated it in 48 hours. Was this necessary?*

A.—Tetanus is an uncommon infection in the dog, and the suggestion that the bite of a dog with tetanus is potentially more dangerous than that of a normal dog has little to support it. The infection is due to the neurotropic toxin of the organism, and this material would not be transmitted in the dog-bite. However, dogs, like other domestic animals, frequently carry tetanus spores in the alimentary canal, and it is therefore a wise precautionary measure to give tetanus antitoxin to any person who has been bitten by a dog. The usual dose is 3,000 units, and this may be repeated a week later if the wound has not healed by then.

Experimental Helminthic Infection

Q.—*With a view to finding an effective anthelmintic against Taenia solium and Enterobius vermicularis I intend experimenting with rabbits. How may these animals be infected—by injection of ova or the adult worm?*

A.—To obtain infection of rabbits with adult *T. solium* it is necessary to feed them on viable and complete cysticerci obtained from measly pork or artificially fed animals; it would be essential to see that each cysticercus was swallowed whole without being bitten. A supply of cysticerci might be obtained by feeding rabbits with gravid segments of *T. solium* broken up in their food, or with mature *Taenia* ova teased out of gravid segments. These would produce cysticerci, which could then be fed to other rabbits. It is doubtful if the rabbit is a suitable host for adult *T. solium*.

The best way to infect rabbits with *Enterobius vermicularis* would probably be to obtain gravid female worms and break them up in the rabbit's food, or tease out the ova and add them to the food.

Therapeutic Value of Yeasts

Q.—*Have the various yeasts—viz., brewer's yeast, baker's yeast, and "food yeast"—different therapeutic values?*

A.—All yeasts are valuable as a source of protein. In considering their therapeutic value, however, we usually have in mind their action either as live organisms or as a source of vitamins. Live yeast is sometimes taken by the public as a

homely remedy for skin eruptions, but it is doubtful whether there is any scientific justification for this, and, if there is, whether any one type of yeast is better than others. The vitamin contents of yeast survive drying or extraction, and vary according to both the type of yeast and the medium on which it has been grown. Vitamin B₁ shows by far the widest range of variation. According to J. C. Somogyi, writing recently in Supplement No. 4 of the *Zeitschrift für Vitaminforschung*, brewer's yeast, which is a strain of *Saccharomyces cerevisiae*, contained 60 to 80 i.u. of vitamin B₁ per gramme of dried material (10% water) when grown on a wort of malt and hops. Baker's yeast, another strain of the same organism, and grown on molasses, contained 20 i.u. of vitamin B₁ per gramme dried weight. In contrast, preparations of *Torula utilis*, which is used for the production of food yeast, contained only 8 i.u. per gramme dry weight when grown in a solution of wood sugar (xylose) and mineral salts. In specially cultivated yeasts concentrations of 250 i.u. of vitamin B₁ per gramme dry weight have been attained. The variations in other members of the vitamin-B complex appear to be relatively slight, but yeasts differ widely in their contents of ergosterol (provitamin D) and of lecithin. There is also a considerable range in flavour, which may sometimes be very bitter, and probably also in the laxative action which has been reported by certain workers who have conducted human trials with specimens of food yeast.

Tuberculous Allergy and Immunity

Q.—Could you briefly explain the significance of difference between allergy and immunity arising (in a child) from tuberculosis?

A.—Allergy is a state of hypersensitiveness produced by tuberculous infection, manifested by an acute inflammatory reaction sometimes going on to necrosis when tuberculin or tubercle bacilli are introduced into the tissues. The element in the tubercle bacillus which elicits this response is a protein. The change yielding this result is in the tissues themselves; it appears not to be dependent on an antibody in the blood, and the condition is certainly not, as in some other forms of hypersensitiveness, passively transferable. Tuberculous allergy may be regarded as a protective mechanism—protective, that is, against reinfection—but it is not the sole basis of immunity. There is a form of immunity distinct from it and presumably dependent, as in immunity to other bacterial infections, on the presence of antibodies in the blood. Experiments have been made in which the two conditions were dissociated, and the desensitized animal has been found to have gained rather than lost in capacity to resist the infection. Although the significance of such experiments has been questioned and the whole subject is somewhat controversial, few would deny that the two conditions are distinct. Immunity operates in the usual way, disposing of the invaders without undue disturbance; allergy, except in so far as it is positively harmful, has a purely irritating function.

Coronary Thrombosis and High Altitudes

Q.—A patient aged 62 had a coronary thrombosis 3½ years ago. He made a good recovery, and his blood pressure is now 140/75. He has a tendency to get short of breath on moderate exertion. Are there any contraindications to his spending a vacation at an altitude of 5,000–6,000 feet (1,500–1,800 m.)?

A.—The fact that this patient had a coronary thrombosis at the age of 58 implies the existence of coronary sclerosis. As he is not troubled with angina of effort and there is no hypertension the prognosis may be regarded as good, although the slight reduction of effort tolerance indicates some impairment of the myocardium. At an altitude of 5,000–6,000 feet the heart has a little extra work to do in maintaining the oxygenation of the body. Coronary syndromes are among the least predictable, but I believe that if no very active pursuits are undertaken the patient will suffer no harm from a vacation at this altitude. He will probably find that his tendency to breathlessness on exertion is a little more noticeable. If he should experience any hint of a return of pain in the chest he should curtail the vacation and return to lower altitudes.

INCOME TAX

Appointment: Car Expenses

R. B. is entitled to a car allowance, as assistant medical officer health, but he regards it as inadequate. (At present he uses a supplied by his employers but intends to buy one shortly.) (C) he refuse the car allowance and claim for tax purposes the interest and depreciation allowances?

*. The statutory rule applicable is that R. B. can deduct expense if it is incurred wholly, exclusively, and necessarily in performance of his duties. Any elements in the expense attributable to private use or the possession of a car superior to one which reasonably necessary would not be allowable. If he receives allowance from his employers the Revenue Authorities are, not naturally, reluctant to regard it as inadequate, and; though R. would be entitled to claim the excess of his allowable expense (including depreciation, etc.) over the amount receivable from employers, they might require the facts to be proved on personal appeal before the Income Tax Commissioners. If he declines car allowance—whether he receives additional pay for that reason or not—the case can be more easily put, but the essential facts would remain substantially the same.

LETTERS, NOTES, ETC.

Treatment of Phlebitis

Dr. R. ROWDEN FOOTE writes: Under your "Any Questions" section (Aug. 17, p. 251) you are asked for the modern treatment of phlebitis. I would like to suggest that the reply excludes some of the modern views on phlebitis. First, regarding phlebitis of superficial veins: since the work of Heyerdale (1943) and many others both before and after it has been accepted that this condition should in the majority of cases be taken to be a direct indication for a high resection of the internal saphenous vein. Provided the inflammation has not reached the last few inches of the vein the operation will produce a dramatic resolution of the inflammatory process. Secondly, when this ideal treatment cannot be offered to the patient I agree that "the limb should be enclosed in adhesive bandages to well above the upper limit of the phlebitis. No mention however is made of the desirability of a sorbo rubber pad over the fossa ovalis. This precaution is an important one. Turning to the condition of deep vein thrombosis, you state that "almost all clinicians still favour a long period of immobilization. Surely with the advent of dicumaryl and heparin modern clinicians have altered their views? I agree that these cases should be kept in bed during the acute and active stage; but this should not be denied the therapeutic benefits both of penicillin and the sulpha series of drugs, neither of which receives notice in your reply.

The Itchy Patient

Dr. S. W. ALLWORTHY writes: The interesting article on The Itchy Patient by Drs. Henry MacCormac, P. H. Sandifer, and A. M. Jelliffe (July 13, p. 48) reminds me of the following: A psychologically normal and elderly patient when suffering from severe and intolerable itching reacted by saying to her husband that, should she go to Hell, she hoped that she would not be tortured by itching. This was rather in contrast to the more hopeful outlook of Oliver Goldsmith's Scotchman who refused to be cured of the itch because it made him unco' thoughtful of his wife and bonny Inverary.

Children in Nurseries

Mrs. G. M. WOOLF writes: The Report of the Medical Women's Federation on the Health of Children in Wartime Day Nurseries (Aug. 17, p. 217) will be studied with the utmost interest, and especially by those who have faith in day nurseries and wish them to well. Thirty-five years ago I became a voluntary helper in a voluntary nursery, and I remember how concerned I was to find that four large handkerchiefs were in common use for the sixty children. I gathered together my courage (I was a novice and just out of my teens) and approached the Chairman of the Nursery Committee. Fortunately for the children and myself she was understanding and sympathetic, and they were each provided at once with a clean handkerchief every day. A simple precaution useful against respiratory infection which one sees adopted in far too few nurseries and nursery schools is that during the afternoon rest the children's stretcher cots should be placed in alternate positions, i.e., the head of one child should lie opposite to the feet of its neighbour.

Disclaimer

Dr. F. HIMMELWEIT writes from St. Mary's Hospital, Inoculation Department, to say that a recent reference to himself and his work on influenza, appearing in a London newspaper, was not inspired by him, and that most of the facts as presented there bear no relation to the true situation. He regards this kind of publicity as most undesirable.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 31 1946

Correspondence

Medical Unemployment

SIR,—I feel I must elbow my way into the discussion on this subject—a serious one, and quite as likely as any other to cause wide rift in the profession on its attitude to the National Health Service and in its answer to the forthcoming referendum.

The facts are, indeed, as the majority of your correspondents have stated, though I have, speaking for myself, had more of the courtesy exhibited so gracefully by the letter of "M.D." (*Supplement*, Aug. 17, p. 65) than other applicants. I have at least had four replies to my scores of letters, and though each of the four was to inform me that the vacancy was filled I appreciated the kindness of the answer from busy men.

Sir, there are hundreds of ex-Service medical men unemployed through no fault of their own. Do not believe that we are being too imaginative in the price we expect for our services or too over-particular in the jobs we obtain and the areas we are to work in. When one's gratuity and other capital is fastbbing away is no time for such niceties. And the older we are the less chance we have in every way. At 40 years of age we are not wanted as assistants and we have so many years the less in which to obtain the necessary money to repay what we borrow for home and practice. If we have to purchase a house by effecting life insurance cover the premiums are, by virtue of our years of war service, so much more expensive that the younger man can step in before us.

There are possibly two sides to the question—but we should not let the matter degenerate into an antagonism between the returned and unemployed ex-Service medical officer and the stay-at-home, overworked practitioner of the war years. That way dissension at this critical moment in the profession's future is certain. A solution must be found.

As an unemployed demobilized ex-Service medical officer I write to thank "M.D." for his letter and to warn the profession at large that unless we are speedily able to find employment—we as assistants, or partners, or in a practice where exorbitant low-payment is not demanded—we shall have no alternative but to ask for speedier negotiations with the Minister, in the hope that we can be found permanent work and financial security. Opponent to the idea of nationalization of the profession though I have always been, I must say "Yes" when I make my answer to the referendum and I must agree to serve in the National Health Service unless a quick way out is found. —I am, etc.,

"PRE-WAR R.A.F.V.R."

SIR,—In medical practice as in many other businesses there exists uncertainty about Socialist plans. As a result, many elderly doctors are working and earning all they can before the calamity of 1948. Many of them should retire, or employ an assistant, but they intend to carry on, and then "get out" in 1948 or when. There is no doubt also that many prospective buyers are nervous: to invest or borrow a large sum, and later find working conditions (under the State) intolerable, leaves one shackled to accept compensation when one is dead as preferable to none at all.

You cannot leave politics out of the argument, and in 1950 the people of this country will settle their own fate after their experiment of July, 1945. This does not excuse men with too much work on hand from getting help, and giving the Serviceman a chance, but let there be no doubt that politics are the root of this, and many of our other troubles.—I am, etc.,

Newquay.

J. P. O'SHEA.

SIR,—Are there many British doctors who like Dr. G. L. E. Thomas (Aug. 3, p. 58) worked in G.P. during the war without finding a permanency, or are there any special reasons for his failure? I was thankful for the sanctuary I found in this country, and when my hope to work as a doctor could not be fulfilled I did not grumble that like many others I had first to live in enforced idleness (1939–1940) and then to work as a labourer in a factory (Jan.–Oct., 1941). Later and up to the present I have held house appointments which included E.M.S. work. I did so by choice, though it would have been much more lucrative to work as an assistant in G.P. I was given a fair amount of responsibility, professional as well as otherwise—for quite a while I looked after German prisoners of war. I was only a little cog, but other alien doctors in this area made great contributions to the work among soldiers and civilians.

At present, when there is some unemployment amongst doctors, the ex-Serviceman comes first. Incidentally, there are some ex-Servicemen amongst alien doctors. We others, like Dr. Thomas and myself, have to take our turn. A number of us alien doctors hope to be British citizens soon; we are all anxious to play a humble part in the magnificently expanding health service of this country, which according to Sir Ernest Graham-Little and others will require many more medical men. Some foreign doctors have already gone back to the Continent, more will follow. A number are anxious to stay for a variety of reasons. I am among the latter, and it is my earnest desire to spare my British wife and son much more uncertainty and anxiety. Personally I received nothing but understanding and kindness from my British colleagues and I would hate to be a trouble to anybody. Nor do I wish to be a scapegoat either.

There are two ways in which we alien doctors can make room now (some are already unemployed). The first one is open to those who are only on the temporary *Register*. Having worked for so many years in this country shall we be admitted to the permanent *Medical Register* right away or shall we have to take a British qualification first? If this question could be settled soon, and perhaps we are expected to sit for a conjoint diploma, we could do our studying now and cease to be competitors for jobs during this difficult interim period. And if it were possible to work for the examination without two to three years' hospital practice (like, for example, a graduate of Cairo or Khartum), we should not be competing with British ex-Servicemen for places at teaching hospitals. The second way is being tried by a friend of mine, a fully qualified man (F.R.C.S., etc.); who is expecting his naturalization any day now. He wants to join the R.A.M.C. Unfortunately he finds it very difficult to get accepted.—I am, etc.,

Manchester.

HERBERT E. BACH, M.D. Vienna.

SIR,—No doubt this is one of many letters you have received in reply to "Principal" (Aug. 17, p. 65). I would like to say that I have been looking for employment such as he offers since February of this year without one reply to my many applications. I am British, ex-Service (5½ years Navy), and an Edinburgh graduate and would gladly start work for "Principal" now under the conditions he offers. Should he still doubt that medical unemployment is a myth let him advertise once more.—I am, etc.,

North Queensferry.

V. C. HASSAN.

SIR,—I was pleased to see the letter from "Unemployed Ex-Serviceman" (*Supplement*, Aug. 3, p. 58). The serious plight of many ex-Service doctors is indeed widespread and distressing, and certainly not appreciated by the majority of the profession. nor, might I add, by the B.M.A. Numerous colleagues whom I have met during the last six months in the waiting-rooms of

the agencies and elsewhere all tell a similar story. Most of us joined the Services at the earliest opportunity after qualifying, and many of us are now married and with a family. Speaking for myself, I have had great satisfaction and experience from my service in the Navy and by no means regret it. But now having left the Service what are the chances of employment? My medical school offers a three months' appointment at £350 per annum—but what then?

If one cared to tie a millstone of debt about one's neck one could purchase a practice or partnership—and usually a house at a price of £3,000 to £6,000 must be bought with it. I have applied for about twenty public health and industrial posts without success; and I applied for seventy-two assistantships, and only two were offered to me—I turned them down as they were both offered by aliens. Sir, what has happened that ex-Service doctors should be unemployed while aliens are sufficiently well established to require assistants?

Believe me, Sir, I am not unique. Yet in spite of excellent professional and Service records and testimonials I remain unemployed. I am told by one of the agencies that for every assistantship vacant they can offer over fifty applicants. As one's bank balance decreases so one's bitterness increases, especially when one sees or hears of colleagues who went from A to B2 and stuck, and who are now (with or without the higher degrees they had the opportunity of taking) comfortably ensconced in lucrative employment, having attained their object of avoiding the Services.

Some time ago I would have seen Mr. Bevan in hell before joining his Service. I regard him now as an angel from heaven who will at least offer me a job with a living wage, which is more than the B.M.A. or the profession seems capable of doing. Roll along 1948. In the meantime,—I am, etc.,

UNEMPLOYED EX-R.N.V.R.

SIR,—May I speak for those young doctors (there must be many of them) who had the misfortune to be rejected by the R.A.M.C. on account of ill-health and who now are out of work? Though not thought fit enough to serve in uniform, we were nevertheless directed to work in hospitals and general practice, at a low salary and for long hours. Now, amid the clamours of the ex-Servicemen, we stand no chance of getting work. But whereas our more fortunate fellows in the Forces were, during their period of leisure, well-fed, well-housed, and paid what seems to us a princely wage, we in our turn have difficulty in finding where to live and are earning nothing.

I submit that conscripted ex-Servicemen should not be given priority over those who were rejected for the Services through ill-health: both should be treated alike.—I am, etc.,

“REJECTED.”

*. These six letters are representative of many others on the same subject.—ED., *B.M.J.*

Delayed Release of Specialists

SIR,—“Ex-Service Medical Officer” (Aug. 3, p. 58) writes utterly about the more fortunate specialists who served with us in the war. They do not deserve this. His bitterness should be directed rather at the fantastic medical system which is debarring the returned doctor from acquiring the much-stressed experience demanded, by the simple expedient of not giving him a job in which he may get his chance of acquiring experience along with his more highly qualified and stay-at-home brothers. After six years in the Forces he may have acquired experience which no years of peacetime work could give him, in the jungle, on the sea, in the front line. But, alas, he has no F.R.C.S., no D.P.H., no D.C.H., no car, so his letters of application will remain unanswered, and, although unable to verify his suspicions, he will be left to assume that the “wartime temporary” appointments have been confirmed in favour of the “wise” doctor who stayed at home and piled up experience in the concrete form of higher qualifications.—I am, etc.,

“EX-SERVICE WOMAN DOCTOR.”

SIR,—We would like to draw the attention of the Central Medical War Committee to the sorry position in which R.A.M.C. specialists find themselves, a year or more after the termination of hostilities. This applies particularly to graded specialists,

to which group we unfortunately belong. While our corresponding groups of general duty medical officers were demobilized four to five months ago, we find ourselves with a further to twelve or even more months to serve in the Army before we can enter civilian practice.

The benefits accrued by our service as graded specialists not very obvious. The practical experience and opportunity for improvement in our specialist branches have been conspicuous by their near-absence. The additional pay, especially taxation, certainly does not compensate for our involuntary delayed release. On the other hand the advantages of demobilization are very obvious, and far outweigh the benefit of being a graded specialist.

Our general duty medical officer colleagues in the Army now in a position to gain experience, to accept available hospital posts, and to study for higher qualifications, the lack of which will prevent graded specialists from competing with them for senior posts in hospitals upon our (eventual) release. Moreover our chances of acquiring practices, if we do not continue in our specialties, are progressively diminishing as more and more G.D. medical officers of far higher A. & S. groups are released from the Army.

Up to the present we have no information (nor is any available from higher authorities) of the approximate expected date of our demob., with the obvious result that we are powerless to make any definite arrangement for our future careers; the uncertainty of the extent of our further service also prevents us getting a definite answer as to whether or not we are eligible to have our families join us overseas.

To sum up, we feel strongly that the R.A.M.C. specialists (especially the “graded” who has not got the qualification to enable him to compete for a senior hospital post immediately on demobilization) is being grossly unfairly treated. Are the Central Medical War Committee and the Army authorities doing all in their power to hasten the demobilization of R.A.M.C. specialists? We believe that this is open to question.—We are, etc.,

B.A.O.R.

“TWO GRADED SPECIALISTS.”

Absent Practitioners' Scheme

SIR,—Now that most of those men in practice before war are back in their practices again, is it not desirable that the names of those who subscribed to this scheme should at least be circulated privately amongst themselves—with the date when they joined, of course!

The new Health Service will mean many committees and is desirable that in electing such, practitioners should know those who refused to share the others' burdens. Otherwise the same astute beings will not be backward in getting themselves into power.—I am, etc.,

Bradford.

THOS. SAVAGE

Functions of an Insurance Committee

SIR,—I have received a letter from the London Insurance Committee which expresses the committee's hope that I “may find a booklet on pulmonary tuberculosis useful.” A copy of the booklet was enclosed. I was not aware that the London Insurance Committee had any function except to administer National Health Insurance. It seems that the committee has been “impressed” by a pamphlet and wishes to instruct ignorant panel doctors in the sort of literature they should read. Is this a sample of the new State Service, when we may expect the Civil Service to direct our medical education and methods of treatment? It is surely wrong that a document published at Tavistock House should be distributed in this way.—I am, etc.,

Welling.

H. G. HOWITT.

*. The booklet in question is by Dr. C. H. C. Toussaint and is published by the National Association for the Prevention of Tuberculosis. Price 1s.—ED., *B.M.J.*

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Mr. John Howkins, F.R.C.S., 109, Harley Street, W.1 (Day, Welbeck 7395; night, Wimbledon 1613); Mr. D. N. Matthews, M.Ch., F.R.C.S., at 152, Harley Street, W.1 (Welbeck 2714); Dr. Kenneth Robson, F.R.C.P., at 57 Wimpole Street, W.1 (Welbeck 0270).

H.M. Forces Appointments

ARMY

Lieut.-Cols. A. J. Beveridge, O.B.E., M.C., and T. H. Sarsfield, B.E., from R.A.M.C., to be Cols.
Lieut.-Col. J. T. Johnson, D.S.O., R.A.M.C., retired and re-employed, has been restored to the rank of Col. on ceasing to be employed.

ROYAL ARMY MEDICAL CORPS

Major (War Subs. Lieut.-Col.) A. N. B. Odbert, O.B.E., to be Lieut.-Col.
Major C. Ryles, O.B.E., retired and re-employed, has been granted the honorary rank of Col. on ceasing to be re-employed.
Major J. V. McNally has retired on retired pay and has been granted the honorary rank of Lieut.-Col.
Capt. (War Subs. Major) D. N. Keys has retired and has been granted the honorary rank of Lieut.-Col.
Capt. J. A. V. Nicoll to be Major.
Capt. C. Reburn has retired and has been granted the honorary rank of Major.
Short Service Commission.—Capt. E. P. Jowett has retired and is being granted the honorary rank of Major.
Short Service Commissions.—Capts. W. Windsor and A. B. Dick have been appointed to permanent commissions.
Short Service Commissions.—War Subs. Capt. J. McQuillan, from A.M.C., Emergency Commission, to be Lieut., and to be Capt. id has been appointed to a permanent commission.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Capt. C. Helm, D.S.O., O.B.E., M.C., having exceeded the age limit, has ceased to belong to the Reserve of Officers and has been granted the honorary rank of Col.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major F. A. Bevan, T.D., has relinquished his commission on account of disability and has been granted the honorary rank of Lieut.-Col.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Lieut.-Cols. (Local Brigs.) M. F. Nicholls and M. L. Rosenheim have relinquished their appointments as Consultants and be local rank of Brig.

War Subs. Capt. R. V. Coxon has relinquished his commission on account of disability and has been granted the honorary rank of Major.

War Subs. Capts. K. W. Leon and P. H. Garrard have relinquished their commissions on account of disability and have been granted the honorary rank of Capt.

War Subs. Capts. G. H. Rosenbaum and K. H. Koster have relinquished their commissions.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Mrs.) L. E. N. Price has relinquished her commission on account of disability and has been granted the honorary rank of Capt.

(Miss) Joan Marsden to be Lieut.

ROYAL AIR FORCE

E. W. R. Fairley has been appointed to a commission as Squad. Ldr. with four years on the active list.

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squad. Ldrs. (Emergency): M. Lentin, D. A. J. Ebrill, A. H. Galley, H. Kopelman, and W. C. Lawrence.

To be Fl. Lieuts. (Emergency): H. W. Bunjé, S. L. Citron, M. E. Winston, J. M. Brown and M. M. Brown.

Fl. Lieut. (Temp. Squad. Ldr.) D. P. Rowe has resigned his commission, retaining the rank of Squad. Ldr.

Fl. Lieuts. W. E. Graham and R. B. Walker have relinquished their commissions on account of medical unfitness for Air Force service, retaining their rank.

To be Flying Officers (Emergency): A. P. Roberts, R. J. Aspinall, J. D. Blainey, E. De M. Connell, T. M. Glaister, L. M. Harrison, D. C. R. Jones, R. H. Little, G. R. McOwan, R. E. Morgan, K. W. E. Paine, D. S. Sharpe, H. R. Smart, N. T. Welford, J. D. Whitehouse, J. E. Davies, D. D. Forbes, R. A. Allen, P. W. Arundell, G. E. R. Bibbings, M. Binnie, R. Burns, E. C. Davies, P. G. Laing, J. G. Latimer, D. J. Lyall, A. Mather, J. D. Paterson, M. J. Peto, N. Rosedale, J. C. Taylor, J. Ward, E. A. Witheridge, H. H. Slack, R. Ellam, E. A. Harris, A. G. Hayter, P. G. Jagger, F. F. Jerichow, A. G. Pollacchi, A. E. Pritchard, G. P. Reed, R. M. E. Seal, S. D. K. Stride, T. C. D. Whiteside, and A. Young.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Fl. Lieuts. M. B. Wizer, E. M. M. Tulloch, and M. I. Greenaway have resigned their commissions, retaining their rank.

INDIAN MEDICAL SERVICE

Majors B. M. Rao, B. N. Hajra, R. M. Lloyd Still, and A. Singh to be Lieut.-Cols.

Major M. G. Leane has retired on account of ill-health and has been granted the honorary rank of Lieut.-Col.

Capt. W. J. Young, D.S.O., M.B.E., J. L. Mewton, L. S. F. Woodhead, M.B.E., J. R. Kerr, J. D. Munroe, W. C. Templeton, G. W. Palmer, B. J. Doran, T. M. Williams, J. F. Thomson, and E. J. Crowe, O.B.E., to be Majors

EMERGENCY COMMISSIONS

Lieut. C. R. Peck to be Capt

COLONIAL MEDICAL SERVICE

The following appointments have been announced: T. H. Bassett, M.B. B.S., A. G. M. Davies, M.B. B.Ch., and D. E. Thompson, M.B. B.Ch., Medical Officers, Tanganyika; Miss A. G. Brodie, M.B. Ch.B., and J. F. McGarrity, M.B. B.S., Medical Officers, Malaya; J. Clark, M.B. Ch.B., D.P.H., J. J. Elbert, M.B. Ch.B., G. F. Houston, M.R.C.S., L.R.C.P., and F. J. Cauchi, M.D., Medical Officers, Nigeria; A. H. Dunnitt, M.B. Ch.B., and J. E. Bosman, L.R.C.P., L.R.C.S., Medical Officers, Gold Coast; S. G. Gordon, M.R.C.S., L.R.C.P., Medical Officer, Gambia; W. G. Timmis, M.B. Ch.B., Medical Officer, Uganda; B. H. B. Upton, M.B. Ch.B., Medical Officer, Fiji; R. K. A. Van Someren, F.R.C.S., Medical Officer, Kenya; R. Wright, M.B., Medical Officer, Nyasaland; S. S. Dryden, M.B. Ch.B., Assistant Medical Officer, Jamaica; J. M. Fitton, F.R.C.S., Orthopaedic Surgeon, Mauritius; S. M. Frazer, M.R.C.S., L.R.C.P., Medical Officer, Bermuda; G. C. A. Jackson, M.B. B.S., Medical Officer, Northern Rhodesia; K. C. Willett, M.R.C.S., L.R.C.P., Trypanosomiasis Officer, Tanganyika; T. A. Austin, L.R.C.P. and S.I. and L.M., D.P.H., Director of Medical Services, Uganda; H. N. Davies, M.B., Ch.B., Medical Specialist, Tanganyika.

MENTAL NURSING SALARIES

HIGHER PAY FOR SENIOR GRADES.

The Rushcliffe Committee has now completed its review of salaries and conditions in the mental nursing services. The provision of new grades is recommended—including those of Deputy Matron (salary from £420-£460 where there are fewer than 330 beds, up to £475-£575 where there are 1,330 or more beds) and Senior Assistant Matron (salary from £440-£480 (330-499 beds) up to £455-£550 where there are 1,330 or more beds). A salary scale of £680-£900, including emoluments of £250, is recommended for Matrons of hospitals or other institutions approved as training schools which have 1,330 or more beds; and increased salaries are recommended also for Matrons and Deputy Matrons in hospitals or institutions which are not training schools. Assistant Matrons, Sister Tutors, Home Sisters, and Housekeeping Sisters also benefit, as does the senior male staff, including Male Tutors. Special consideration has been given to student mental nurses who have been on war service.

All salary increases are retrospective from Jan. 1, 1946. Half their cost will be met by the Ministry of Health.

Meetings of Branches and Divisions

BATH DIVISION

A meeting of the Bath Division was held on Aug. 15, with Dr. G. D. STEVEN in the chair. The secretary informed the meeting that the following three resolutions passed at the meeting of July 17 has been sent to the Council: *Motion I.*—That this meeting of practitioners of the Bath area gives its full support to the three resolutions passed by overwhelming majorities at the Special Representative Meeting on May 1 and 2, 1946, viz.—(i) That the remuneration of general practitioners under any National Health Service should take the form of an adequate capitation fee without a fixed part salary, and without a tapering scale of payment. (ii) That this meeting regards as essential to the freedom of patients and the profession the right to buy and sell practices as at present. (iii) That there shall be no control over doctors in regard to the choice of area in which they shall practise. *Motion II.*—That this meeting of practitioners of the Bath area urges the Council of the British Medical Association to submit a preliminary referendum to all members of the profession immediately after the National Health Service Bill is passed. And that that part of the referendum dealing with general practitioner service should be based upon the acceptance or rejection of the three main clauses, viz.—(i) Payment by capitation fee only. (ii) The right to continue to buy and sell practices. (iii) No control over doctors as regards the area in which they shall practise. *Motion III.*—That in returning the proposed referendum each individual should be asked to state to which group of the profession he or she predominantly belongs, viz.—A. general practitioner, B. consultant, C. public health.

Dr. R. G. GORDON, the representative of the Division, gave an account of the Representative Meeting which had just been held, and this was followed by considerable discussion.

INSURANCE CAPITATION FEE

A special meeting of the Insurance Acts Committee was held on July 22 to consider an offer by the Minister of Health, orally communicated to the Committee's representatives on July 17, of an increase in the capitation to 12s. 6d., with retrospective effect from Jan. 1, 1946. A letter containing this proposal was received from the Ministry within an hour of the meeting (*Supplement*, July 27, p. 31). At the meeting the following resolutions were carried unanimously:

1. "That the Minister be informed that the Insurance Acts Committee, while it welcomes the Minister's acceptance of the majority report of the Spens Committee and his recognition of the inadequacy of the capitation fee, regards the proposed increase of the capitation fee to 12s. 6d. as gravely inadequate."

2. "That the Minister be informed that the Insurance Acts Committee would be prepared to recommend insurance practitioners to accept in the interim a capitation fee of 15s., retrospective to January 1, 1946. The Committee would be willing, if the Minister so prefers, that the Spens Committee should be asked to state the implications of its majority report in relation to the current insurance capitation fee on the understanding that the Minister and the Insurance Acts Committee accepted, in advance, the findings of that Committee."

The action taken by the Insurance Acts Committee was approved by the Annual Representative Meeting on July 25 (*Supplement*, Aug. 3, p. 53). There has now been issued by the Ministry of Health the following circular, which is addressed to the clerks of insurance committees.

CENTRAL PRACTITIONERS' FUND, 1946

Increase in the Capitation Fee Payable to Insurance Doctors

1. I am directed by the Minister of Health to say he has decided to increase the amount of the capitation fee payable to insurance doctors from 10s. 6d. to 12s. 6d. as from January 1, 1946.

2. The effect of this decision is to increase the Committee's share of the central pool for 1946 from the provisional amount shown in Paragraph 5 of the Department's circular letter (I.C.L. 1250) of March 8 last to £..... The Committee should accordingly arrange for payment to be made to insurance doctors for the current quarter on the basis of this revised amount and for the necessary additional payment to be made at the same time, if possible, or as soon afterwards as practicable, in respect of the first two quarters of the year. Application for funds to meet these payments should be made to the Ministry forthwith on the appropriate form.

3. The additional sum of six shillings per annum in respect of persons discharged from His Majesty's Forces on medical grounds remains unchanged, and the total fee in respect of such persons will be 18s. 6d. in place of 16s. 6d.

4. A form of notice (G.P. 119) announcing the increase is in course of preparation, and a supply for issue to resident doctors on the Committee's medical list is being forwarded to you under separate cover.

5. The fee of 10s. 6d. mentioned in the fourth paragraph of Circular Letter I.C.L. 1259 of June 26 last as the capitation fee in respect of unaccompanied evacuee children billeted on householders in reception areas will also be increased to 12s. 6d., but the Committee will be concerned only with the period from July 1, 1946, and payment for the current quarter should therefore be on the revised basis of 3s. 1½d. (exclusive of payment in respect of drugs and appliances and mileage).

The position will be reconsidered by the Insurance Acts Committee on Sept. 5.

Association Notices

Sir Charles Hastings Clinical Prize

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of fifty guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own

observations in practice rather than to comments on previous published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1946. The prize will be awarded at the Annual General Meeting of the Association to be held in 1947.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto, and enclosing the candidate's name and address.

8. The writer of the essay to whom the prize is awarded may, at the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9. Inquiries relative to the prize should be addressed to the Secretary.

POSTGRADUATE NEWS

A series of meetings will be held in the Department of Ophthalmology of the University of Glasgow on Wednesdays, at 8 p.m. from Sept. 11 to Oct. 16, both dates inclusive, and will be open to all medical practitioners and senior students interested in ophthalmology. Details will be published in the diary column week by week.

APPOINTMENTS

LONDON COUNTY COUNCIL.—The following appointments have been made to the mental health services of the Council at the hospitals indicated in parentheses. *Deputy Medical Superintendent*: B. H. Kirman, M.D. (Fountain). *First Assistant Medical Officers*: E. N. Butler, M.R.C.S., L.R.C.P. (Ca Hill); J. M. Crawford, M.D. (St. Bernard's); Pauline W. M. C. Stirling, M.B., Ch.B. (Friern); G. M. Tucker, M.B., Ch.B. (Darenth Park).

KENT AND SUSSEX HOSPITAL, TUNBRIDGE WELLS.—Honorary appointments: *Physician*: J. H. Easton, M.D., M.R.C.P. *Pediatrician*: N. M. Jacob, M.B., B.S. *Assistant Ophthalmic Surgeon*: H. M. Symons, M.B., B.S. *D.O.M.S. Anaesthetist*: P. T. Ashby, M.B., B.Ch., D.A.

ROYAL SHEFFIELD INFIRMARY AND HOSPITAL.—Honorary *Physicians*: H. Brody, M.R.C.P., A. W. D. Leishman, D.M., M.R.C.P., E. Skipper, M.I.M.R.C.P.

TIMBLES, SYDNEY G., L.R.C.P.&S.Ed., Eye Specialist to Kent County Council for clinics at Beckenham and West Wickham, and to the L.C.C. Hammersmith.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

CURNOCK.—On August 17, 1946, to Vera (née Bucknell), wife of Dr. H. H. Curnock, 136, Wanstead Park Avenue, E.12, a son—David Anthony.

FERGUSON.—On August 11, 1946, at Avondale, Woodbourne Road, Douglas, I.O.M., to Frances (née Wright), wife of Dr. J. H. Ferguson, a daughter—Elizabeth Ann.

KELLY.—On August 18, at 5, Cator Road, London, S.E.26, to Peggy, wife of Dr. Reginald Kelly, a son—Christopher William.

LANKESTER.—On August 21, 1946, at Oxted, Surrey, to Mary (née Burnett), wife of Dr. John Lankester, a son—Thomas Edwin.

MCALPIN.—On August 20, 1946, at Great Yarmouth, to Dorothy (née Goldsmith), wife of Surg.-Lieut. J. M. McAlpin, R.N.V.R., Royal Naval Hospital, Great Yarmouth, a son—Robert John.

SMITH.—On July 18, 1946, to Valentine, wife of Dr. R. W. Smith, a daughter—Rosemary Ann.

WILSON WILLIAMS.—On August 18, 1946, at Cardiff, to Betty, wife of Capt. R. Wilson Williams, R.A.M.C., B.A.O.R., a son.

MARRIAGES

MCCLAREN—TAYLOR.—On August 10, 1946, at Irish Church, Kingraigh, Invernesshire, Flying Officer William James McLaren, M.B., Ch.B., to Pauline Annette, only daughter of Mrs. E. B. Taylor, of Cricklewood, London.

MORT—WESTON.—On July 18, 1946, at Sale, Cheshire, Philip Mort, M.B., B.Chir., M.R.C.S., to Sybil Weston.

DEATHS

CAMPBELL.—On August 14, 1946, at Radcliffe Infirmary, Oxford, John Fort Campbell, L.R.C.S.&P.Edin., L.D.S.Edin., of Forest Lodge, Totton, Hanover, after a short illness.

COWARDIN.—On August 3, 1946, at Portsmouth, William Lewis Cowardin, M.R.C.S., L.R.C.P.Lond., Surg.-Commander, R.N. (retd.), the dearly loved husband of Edith Cowardin.

MIGRAINE AND THE SYMPATHETIC NERVOUS PATHWAYS

BY

G. F. ROWBOTHAM, B.Sc., F.R.C.S.

Neurosurgical Unit, Newcastle-upon-Tyne

he pain of migraine is probably due either to excessive spasm or to dilatation of the arteries of the scalp and dura mater. It has been shown that the painful impulses are, in some cases, conveyed to the brain through the upper half of the posterior root of the trigeminal nerve on the same side, and so the trigeminal pathways may be regarded as a sensory arm of the migraine cycle" (Rowbotham, 1942).

What is not known is why the arteries concerned occasionally contract or dilate excessively. One theory is that a migrainous person is born with an unstable mechanism in the hypothalamus which reacts excessively to the multitudinous stimuli that reach it, either from the higher centres or through the blood stream, and causes explosive or dysrhythmic messages to be sent to the large blood vessels of the head. It is an anatomical fact that these large blood vessels are supplied with motor fibres from the efferent side of the autonomic nervous system. Therefore, if disordered messages from the hypothalamus are in fact transmitted by the motor autonomic pathways to the vessels concerned, then section of those pathways should give relief in cases of migraine.

Experiments to Test Hypothesis

The following series of experiments was designed and carried out to test the verity of this supposition.

Case I

This concerns a young doctor aged 30 years. The history is that from the age of 8 he had suffered from periodic headaches. At the age of 14 he began to study for matriculation and higher school certificate, and from then onward the headaches became increasingly severe and more frequent. He obtained a scholarship into a medical school and finally qualified M.R.C.S., L.R.C.P., intending later to sit for a university degree. In the postgraduate period his headaches became so severe that he became virtually incapacitated, and on occasion suffered pains in the head which lasted for five days or more. His condition apparently was hereditary, as his mother, grandmother, and great-grandmother had all suffered from migraine.

Typically, an attack of headache would be preceded by hallucinations of light in the right homonymous field which ended in a complete right homonymous hemianopia. The hallucinations of light would, on the average, last for twenty minutes, and the homonymous hemianopia for about an hour. Occasionally tingling feelings would also be felt in the right hand and the right leg. Sometimes, during an attack, the right pupil would be contracted and the right side of the face flushed. One hour or so after the onset of the visual hallucinations a pain would start as a burrowing sensation in the region of the left temple, and as the pain became more severe it would radiate backwards and forwards until the whole of the left side of the head was affected. Only rarely did the headache extend to the right side of the head. Sometimes the pain on the left side radiated into the upper part of the face. A feeling of nausea was usual during an attack, but actual vomiting was only occasional. After the attack was over the left side of the scalp was sore and accommodation of the eyes was difficult. The attacks of headache might occur without being preceded by visual hallucinations.

On examination the patient was found to be a man of good intelligence; mentally alert in every way, quick to answer questions, and quick to appreciate the logic of an argument. He showed no sign of nervousness when being closely cross-questioned. All his movements were smoothly co-ordinated, and the pulse was normal in rate and rhythm. No abnormal neurological signs were found, and later special investigations and tests failed to reveal any abnormality in the head or in the general metabolic processes. Though it was realized we might be dealing with a cerebral vascular anomaly of the arteriovenous type, we felt that angiography was not called for.

Diagnosis.—From the periodicity of the head pains and the premonitory visual hallucinations there was little doubt that we were dealing with a case of migraine. Moreover, in view of the long-standing history and the absence of abnormal physical findings, it was justifiable to regard the migraine as being of the idiopathic or primary type.

At a neurological clinic elsewhere, full investigations had been made and a diagnosis arrived at of a psycho-neurosis of the anxiety type. Moreover, in the near past my patient had been taking excessive quantities of analgesic and soporific drugs, and had on this account been in trouble with higher governmental authorities. The doctor admitted that he was highly strung, and agreed that his headaches were almost invariably precipitated by some psychological activity. What he was adamant about was that it was mental excitement or exhilaration which led to trouble, and not a sense of depression. When fully enjoying himself, making investigations into a problem which particularly interested him, he would be struck down by a violent headache and left incapacitated for a week or more. He had no objection whatever to the periods of mental exhilaration; it was the pain, and only the pain, which incapacitated him. His father was also of the same opinion, and thought that his son could become satisfactorily readjusted and resocialized if he could be relieved of what he considered to be physical pain.

After having made careful observation, I came to the conclusion that, whatever this man's psychological state, he was suffering from the condition which we know as migraine. In view of this decision and the fact that all kinds of drugs, including ergotamine tartrate, had been given an extensive trial, I decided that some kind of operation was necessary.

Operation, Feb. 14, 1945.—Under general anaesthesia, the patient lying on his back with the head turned to the right, an incision was made along the anterior margin of the left sternomastoid muscle, starting at the tip of the mastoid process and extending downwards as far as the thyroid cartilage. The carotid sheath with its enclosed vessels and the vagus nerve were isolated and retracted backwards, the sympathetic chain between the middle and upper cervical ganglia was exposed and divided, and the lower half of the upper cervical ganglion was removed. The outer coats of the common internal and external carotid arteries were stripped and removed in the manner of Leriche's periarterial sympathectomy. Finally the external carotid artery was clamped and divided between two ligatures (Fig. 1). The wound was re-formed in layers without drainage, and the patient made an uninterrupted recovery from the operation.

The following is a series of statements taken from the progress reports. Feb. 28, 1945: "Since my operation 14 days ago I have been perfectly free from symptoms of headaches and visual hallucinations." May 13: "The operation on the left side has so far

proved an unqualified success. In these last three months I have not had the slightest trouble in any way with the left side." May 31: "I have had five right-sided headaches since I last wrote you, but no trouble at all with the left; otherwise I am keeping pretty fit."

FIG. 1.—The operation of high cervical ganglionectomy and periarterial sympathectomy. (The part of the ganglion and sympathetic chain removed is shown by shading.)

Operation, June 20, 1945.—On account of the fact that the right-sided headaches were increasing in frequency and severity, and because of the apparent success of the left-sided sympathectomy, it was decided to carry out a similar operation on the right side of the neck. The details and technique were the same as those of the previous operation.

The following are extracted from the progress reports. Sept. 12, 1945: "I must tell you that the effect of the second operation, and therefore of the two combined, has been truly dramatic: it gives me very great pleasure to be able to tell you that every symptom the migraine has completely vanished. There has been no further of pain on either side; the visual fields have cleared completely; there are no longer any hallucinatory or defectual faults of vision. All throbbing and tenderness along vessels and in the scalp have vanished. I can now go to the cinema, indulge in hot and cold baths, etc., with impunity." Nov. 18: "I am happy to be able to tell you that I am still completely free from all migrainous symptoms: especially so now that I am doing a full-time job." Feb. 18, 1946: "I am happy to be able to tell you that I am still absolutely without symptoms and signs of migraine in any form. I have put on 18 lb. [8.16 kg.] in weight, I sleep like a log, and I am generally more placid and far less excitable than I used to be." May 8: "I have great pleasure in informing you that I am still quite free from any sign or symptom of migraine."

Case II

A young man aged 21 years, whose illness commenced in 1942 while he was in Gibraltar serving with the Navy in a non-commissioned rank. For many months he had been on convoy duty between Gibraltar and Malta. One night, for no special reason, he developed a very severe headache, but after a time was able to get off to sleep; that same night he woke up and vomited. The next night he had another severe headache, which was also associated with vomiting, and this was followed by a period of lassitude which lasted for about two days. On account of the frequent recurrence of the headaches he was returned to the British Isles and finally had to be discharged from the Services.

I first saw him on Jan. 18, 1945, at the Retreat Hospital, York, at the request of my friend Dr. Pool. It was Dr. Pool's opinion that this man was suffering from neither a psychosis nor a psychoneurosis; in fact, he had come to the conclusion that his patient was suffering from a serious organic lesion and possibly from a cerebral tumour.

On my first examination I found the man to be fully and easily co-operative, to be quick and alert in every way, and that he revealed no obvious signs of psychoneurosis. Neurologically there were no abnormal signs. He was admitted to the Neurosurgical Unit on Feb. 1, 1945, for observation. After a day he began with

very severe left-sided headache which made him vomit, and during the height of the painful attack he developed a left external rectus palsy which persisted for 36 hours.

Full investigations were carried out, and these failed to reveal any organic abnormality in the head or in the general metabolic processes. Although the probable existence of a vascular anomaly of the aneurysmal type was borne in mind, an angiogram was not made. In spite of adequate medical treatment, including injections of ergotamine tartrate, the headaches came on at intervals of about two days, and the pain was so exceedingly severe as to be completely incapacitating. On one occasion it was necessary to inject morphine to give him relief. Later he was transferred to the rehabilitation centre in the hope that a change of air would relieve his symptoms, but within two weeks he was returned to my care still complaining of severe pain.

Diagnosis.—In view of the unilateral character of the pain, its periodicity, and the temporary ocular paralysis, there could be little doubt that this was a case of migraine. Moreover, as no physical abnormalities could be demonstrated, it could be classed as idiopathic or primary migraine. Because of the severity of the pain, and the fact that it had been causing the man to take large quantities of analgesic drugs, I decided to operate.

Operation, March 14, 1945.—The following procedure was carried out: (a) Removal of the lower half of the upper cervical sympathetic ganglion and the chain below it; (b) stripping of the outer coats of the external and internal common carotid arteries; (c) ligation and division of the external carotid artery.

After the operation wound had healed the patient was transferred to the rehabilitation centre, where he remained for two months. During this period he had no recurrence of the headaches, and the medical report from the matron was satisfactory in every way. After a short stay at home he volunteered to the Society of Friends to go to Burma as an ambulance driver. However, on advice he found work on the land, and has been in full-time agricultural employment ever since. He occasionally gets a sense of discomfort on the left side of the head, but he has had no more severe head pains; moreover, he has no need to take analgesic drugs and finds that he has no desire to indulge in them.

Case III

A woman aged 38 years, an assistant matron in a general hospital. The history was that at least six years ago she started to suffer from attacks of right-sided headache and had, in fact, been off duty for long periods because of the pains. The headache would start slowly in the right temple or in the right forehead, and gradually increase in severity and spread until the whole of the right side of the head was affected. It was preceded or accompanied by spots in front of the eyes and by photophobia. Often she felt sick, but only occasionally did she vomit. In the early years of her illness the pain would disappear after a quiet rest, but in later years the headache had lasted for several days. Attacks were particularly liable to occur about the time of menstruation.

On examination she was found to be an intelligent woman and in every way satisfactorily co-operative. Though anxious about her present state of ill-health she showed no signs of a formal psychoneurosis. Neurologically no abnormal signs were found, and full investigation failed to reveal any abnormality in the head or the general metabolic system.

Diagnosis.—There was little doubt that here we were dealing with a case of migraine of the idiopathic or primary type. In view of the severity and frequency of the headaches I decided that operation was justifiable.

Operation, July 11, 1945.—This consisted in (a) removal of the lower half of the upper cervical sympathetic ganglion and the chain below it; (b) stripping of the outer coats of the external and internal common carotid arteries; (c) ligation and division of the external carotid artery.

Shortly after operation she was able to return to work, and the following is a statement from her on Oct. 18, 1945: "I am very pleased to say I have been free from attacks since the operation. I shall never be able to thank you for all you did for me; words cannot express my appreciation." I saw her again on April 3, 1946, and she said that the operation had been a great success. She had been able to stay on duty continuously. On one occasion she developed a pain in the head similar in character to the ones she had before the operation, but it was very much lighter and within an hour or so it passed off. She has had a lot of what she describes as "little headaches," which begin as though major attacks would follow, but these soon disappear and do not develop into actual pain.

Case IV

This was a young man aged 29, a lieutenant in the Army. The history is that, as far back as he can remember, he has suffered from headaches of varying degrees of severity. Until 1935 the pain had never been so severe as to incapacitate him completely or to

compel him to go to bed. In 1940 the headaches became more frequent and increasingly severe, and it was noticed that they were particularly liable to occur on Sundays. He entered the Services in August, 1941, and was put into Grade A1. From then until 1943, though he had attacks of headache, he did not have any serious incapacitating head pains. The first really bad attack occurred in the early summer of 1943, and because of a repetition of the severe headaches he was sent to a military hospital for further investigations and for treatment. There a diagnosis of migraine was made by the attending neurologist, and he was put on a course of analgesic drugs. During the winter of 1944 he had a series of extremely bad headaches, and these he attributed to excessive work and the fact that he had to deal with a difficult commandant.

In the past year the headaches have been coming on at intervals of from three to six weeks. He has never been able to discover any definite cause, but he has noticed that there is a tendency for them to occur whenever he has been mentally excited—for example, after an enjoyable evening spent with friends. He is a teetotaler and smokes fewer than 20 cigarettes a day. It was discovered that the only two drugs which gave him any real relief were ergotamine tartrate injected intramuscularly early in an attack, or enough morphine to put him to sleep.

In a typical attack he gets a feeling of discomfort in the head the night before the onset; he wakes up the next morning with a general kind of headache which later becomes intense, and a pain develops in the right temple, gradually spreading all over the right side of the head. The pain is stabbing in nature, and when at its height is almost unbearable; it is also of a throbbing character and occasionally spreads into the right side of the face. Any kind of head movement aggravates the pain; during an attack he finds it difficult to focus his eyes, but he has never been troubled with double vision, spots, or light; he has vomited not more than three times, and then only after the giving of morphine or of fergemin.

On examination he proved to be above average intelligence, and in no way unduly emotional. He was obviously highly strung, but there were no frank psychoneurotic tendencies; certainly there was no desire to escape from his duties, and the one thing he wanted was to remain in the Services. The headaches troubled him chiefly because they interfered with his capacity to carry out his duties efficiently. Neurologically I could find no evidence of any organic intracranial lesion. Special investigations and tests failed to demonstrate any abnormality in the head or in the general metabolic processes.

Diagnosis.—In view of the periodicity and the long history of the head pains there could be little doubt that we were dealing with a case of migraine; moreover, it was probably of the idiopathic type, because no underlying pathological lesion could be demonstrated.

Operation, Aug. 10, 1945.—In this case removal of the whole of the upper cervical ganglion, stripping of the outer coats of the common internal and external carotid arteries, and ligation and division of the external carotid artery were carried out. Appended are copies of the follow-up reports.

Sept. 16, 1945: "I had an attack of right-sided headache to-day, which was similar in every way, neither more nor less severe, to those I experienced prior to the operation." Oct. 24: "The operation has afforded me no relief from my headaches." Dec. 12: "I am still having occasional right-sided headaches of the type similar to those I had before I was operated on." Dec. 31: "I am convinced that the attacks are now less frequent and, if anything, a trifle less severe than at one time. I find that I am able to go about without the fear of an attack materializing. I have occasional stabs of pain, or a dull ache for some while in either left or right temple, but I am now, disregarding these, as they have not led to further trouble."

Feb. 3, 1946: "As mentioned to you when I was in Newcastle last, I am of the opinion that the operation has been of some help. Whether it is that I am now taking the precaution of having something done before the attack becomes too serious for the fergemin to take effect I cannot say, but certainly no attack, since the one on Sept. 16 last, has been so severe as those experienced before. On this occasion, however, you will see from the report that I was unable to obtain fergemin, and morphine was administered only at night. There would not appear to be much difference in the frequency, except that at times, of course, in the past there have been periods when I would have attacks two or three times during the month. This, however, has only been exceptional." Feb. 23: "There have been no other attacks, severe or mild, during the month, so there is little to report. One thing does amaze me, however, and that is that the attacks in over 75% of cases occur on a Sunday. It does not seem to matter where I am or where I have been. You will recollect that the last attack prior to the operation was on a Sunday, whilst in hospital. It does not seem material, therefore, that any particular place, work, or happenings have any bearing upon this aspect, which always has appeared to me to be very mysterious."

Comment on the Operations

In all four cases the nervous tissue removed was proved by histological section to be sympathetic ganglia and lengths of the sympathetic chain. In all cases the patient was left with Horner's syndrome, and dryness of the face and of the nasal air passages on the operated side. In no case was the carotid body itself removed, though, of course, its connexions must have been extensively severed. The identity of the external carotid artery was established, both by its position and by demonstration of its lower branches. In Case IV the patient complained of a persistent and unpleasant sense of stuffiness in the dried nostril, and this complication is a serious disadvantage of the operation. In Case I, following the second operation, the patient developed paralysis of the vocal cord due to retraction of the vagus nerve. Recovery is now taking place.

Assessment of the Pain

The Amount of Pain.—Though electrical disturbances can be measured in peripheral nerves when pain is being conducted

FIG. 2.—The "migraine cycle."

along their pathways, the amount or severity of pain cannot be precisely measured in scientific units. We depend for our assessment on how much a patient complains, on how the pain affects his happiness and human relationships, and how it affects his ability to work.

Its Relief.—Assessment of the result of the relief of pain depends partly on the patient's own statement, on his ability to enjoy himself, on the way he is socialized, and on how he can carry out his work. The possible objection that at least two of the patients in the above series were suffering from a psychoneurosis rather than migraine is not a strong one, because psychoneurotics are rarely cured, or relieved for any length of time, by a simple incision in the neck. Moreover, a disordered mental state can precipitate the "migraine cycle."

If it is true that (1) the pain of migraine arises in the arteries of the head from excessive spasm or dilatation, that (2) the pain in some cases is transmitted to the brain through the upper part of the posterior root of the trigeminus, and that (3) the arterial spasm is aroused by dysrhythmic messages passing along the

motor sympathetic pathways, then a neural mechanism can be constructed which will account for many of the phenomena in migraine. Fig. 2 illustrates this possible mechanism.

That the hypothalamus exists is an anatomical fact; that certain of its cell clusters can, with suitable stimulation, affect the calibre of the peripheral arteries is also a fact. The hypothalamus can be stimulated by chemical changes in the blood stream which reflect changes in general metabolism, and by messages of the intellect and emotions from the higher centres. If the hypothalamic mechanism happens to be in unstable equilibrium it can react abnormally to all kinds of stimuli and transmit dysrhythmic messages to the peripheral blood vessels, and particularly to those of the head. Possibly, therefore, a central unstable mechanism is the essential cause of migraine; all other stimuli, too much or too little of this and that, being merely precipitants or initiators of the "migraine cycle." The connexions of the hypothalamus with the peripheral anterior pathways are not known. They are, however, believed to lie deeply within the brain stem and spinal cord. The peripheral motor sympathetic pathways are known, and the main neuro-anatomical details are depicted in Fig. 1.

By my own previous experiments it has been shown that in some cases the pain pathways are transmitted through the upper part of the trigeminal root on the same side. It is known that no nerve fibres enter the posterior root other than through the ganglion, and no fibres enter the ganglion other than through the divisions of the nerve. Therefore, since the fibres of the ophthalmic division are represented in the upper part of the root, the pain pathways in migraine must traverse the ophthalmic division of the trigeminal nerve. Where precisely the pain pathways enter the ophthalmic nerve is not known. Moreover, it is not known whether the blood vessels themselves are supplied with pain fibres. This, however, is merely a point of academic importance, because radicles of the trigeminal nerve so closely follow the vessels that, even if they do not supply them, they could easily be stimulated by changes in their calibre.

In Case IV the fact that peripheral sympathectomy failed to cure possibly means that the unstable mechanism in this case lay in the vessels themselves and not in the hypothalamus. Another possible reason for failure is that the whole, and not the lower half only, of the upper cervical ganglion was removed.

CRASH HELMETS*

BY

Sir HUGH CAIRNS, K.B.E., D.M., F.R.C.S.

My interest in crash helmets arises solely from the fact that during the war I spent a considerable part of my time treating injured motor-cyclists at the Military Hospital for Head Injuries at Oxford. In other words, it was the segregation of the Army's head-injury patients in special centres which made possible the prompt recognition of the importance of crash helmets. In subsequent work on the subject I was fortunate in having as collaborator my colleague at Oxford, Dr. Holbourn, who was a motor-cyclist as well as a physicist.

In 1940 we observed that a large proportion of our head-injury patients were motor-cyclists: of the first 290 patients with blunt head injury 70 were motor-cyclists. Of these 1 died, 10 were invalided from the Service, and the remainder were absent from duty for an average period of four months. There were at that time no medical statistics relating to motor-cycle accidents, but the records of the Claims Commission showed that about 600 motor-cycle accidents occurred in the Army at home each month. The total death rate in the country was mounting: in the first 21 months of the war 2,279 motor-cyclists and pillion passengers were killed on the road—over 3 a day—and calculations showed that to this death roll the Army was contributing about two-thirds. With the help of the Royal Society for the Prevention of Accidents, and the Registrar-General, we found that head injury was present in 92% of a series of 111 fatal cases, and, though not the sole cause of death, was clearly a major factor in the majority.

In 1940 the Army already had some crash helmets. These were issued only to certain types of motor-cyclist, and some were of canvas and others were meant for use in armoured vehicles. Some motor-cyclists wore the ordinary steel helmet. In 1940-1 only 1 in 20 of our motor-cyclist patients at Oxford had been wearing crash helmets at the time of the accident, but in these the relative mildness of symptoms was impressive enough to justify a report to the Director-General of the Army Medical Services, and to the Military Personnel Research Committee of the Medical Research Council, who were at that time considering helmets (Cairns, 1941).

In November, 1941, the Army Council made the use of crash helmets compulsory for all motor-cyclists. The R.A.F. followed suit in 1942. Whether the Royal Navy took any action I do not know—which is perhaps a humble argument in favour of a combined medical service. After recommendation had been made and action taken, by the end of 1942, we had accumulated enough evidence to prove that crash helmets were really very effective, and also to show how they might be still further improved (Cairns and Holbourn, 1943). This is an example of the impelling need for hasty decision in wartime on questions which really should have been worked out thoroughly between the wars.

The medical interest in crash helmets would have had no immediate effect if the Army, by the end of 1941, had not had crash helmets ready to supply all its 100,000 and more motor-cyclists in this country. The fact that it had got them may have been influenced to some extent by the early medical reports, but was, I suspect, mainly due to the example, before the war, of the racing motor-cyclists and men like A. B. Bourne and Graham Walker, who helped the Army to build up its motor-cyclist training. From about 1921 the Auto Cycle Union had made the wearing of crash helmets compulsory at speed trials, and their standard laminated fabric helmet is still one of the best available. When we began to treat Army motor-cyclists at Oxford we naturally got to know their comrades—keen motor-cyclists in the Army Training Schools, Royal Corps of Signals, and other units, who were very much alive to the wastage of their man-power from accidents, and they needed little encouragement to become enthusiastic advocates of compulsory use of crash helmets.

Structure and Mode of Action of the Crash Helmet

The components of a crash helmet are a firm outer shell, and an inner sling and hat-band which act as buffers. To understand the action of crash helmets it is necessary to consider what happens in a blunt head injury. There are two important effects of the blow: (1) the local injury beneath the site of the blow; (2) distortions in parts of the brain remote from the blow which depend on sudden change of velocity of the head.

At the site of the blow the scalp may be torn, the skull bends and may break, and fragments of it may penetrate the brain; and the brain may be bruised as well as torn. According to Holbourn (1943, 1944, 1945), when the head is made to rotate suddenly by a blow from a moving object, or against a stationary one, the brain, not being a rigid structure, lags behind. The brain makes the only kind of movement possible to a highly incompressible substance in an enclosed space—namely, a swirling movement—and the surface of the brain slides along inside the cranial cavity. These sliding movements of the surface of the brain have been observed with a high-speed camera and a perspex window in the skull, using the technique of Shelden *et al.* (1944). The movements set up shearing stresses in various parts of the brain; they are most severe where the lesser wing of the sphenoid juts into the cranial cavity, and it is in this region that bruising and laceration of the brain are so often seen, no matter where the blow has been struck. The clinical state of concussion is clearly due to remote effects, since it does not arise from the local brain injury of many gunshot wounds or of surgical operations.

The crash helmet modifies both the local and the remote effects. Locally the shell of the helmet spreads the blow over a wide area and protects the scalp and skull from the pointed pieces of road metal or whatever object is struck. In some cases it prevents fracture of the skull; in others, where a fracture is produced, it prevents the fracture from becoming

* Read at the Royal Society of Medicine, March 20, 1946.

depressed. The shell lessens bending of the skull, and therefore the local bruising of the brain. The shell also lengthens the blow—i.e., spreads it over a longer period of time. It does this by sliding over the surface struck, instead of stopping more abruptly as the unprotected head would do owing to its greater coefficient of friction, and by means of the buffering action of the slings and hat-band. The blow is also lengthened to some extent by rotation of the helmet relative to the head.

So far as the remote injury is concerned, spreading the blow over a larger area does not diminish the rotational velocity, but spreading the blow over a longer interval of time reduces the total force at any instant and thus lessens the remote effects.

Types of Helmet

The two main types of helmet used by Army motor-cyclists—the vulcanized rubber helmet and the pulp helmet—have previously been described, together with examples of their behaviour in various accidents (Cairns and Holbourn, 1943). The pulp helmet is at least twice as good as the rubber helmet. In addition there are the Army steel crash helmet and the leather helmet used by motor-cyclists of the National Fire Service.

The importance of adjusting the fit so as to obtain maximum protection of the forehead and sides of the head, the need to have the chin-strap buckled and to maintain all parts of the helmet in serviceable condition, have been emphasized in Army Council Instructions and Training Memoranda.

Observations on Head Wounds

In the course of this work we found that it was possible, from the marks on the helmet, to determine the site of the blow, as there was the closest correspondence. In 91 cases over 50% of the blows were on the front half of the helmet and very few on the crown. In 40% the head received more than one blow. Blows in the occipital region, which is protected by the helmet and by the neck muscles, were least dangerous, and blows in the temporal region, which is not very well protected by the helmet, were most dangerous to life.

Results

In estimating results we were hampered by being able to observe only the hospital population of injured motor-cyclists. We had no figures of the motor-cyclists whose injuries were so slight that they were not admitted to hospital, or of those who died before admission to hospital (20% of one group of 46 fatal cases in Southern Command). However, on evidence which we have already published (Cairns and Holbourn, 1943), we concluded that the incidence of fractured skull was reduced to one-quarter by the pulp helmet, and the severity of such fractures as occurred was demonstrably less. The effects of concussion were also modified by crash helmets, as the incidence of prolonged amnesia after injury was only one-third of its incidence among those who had not worn a crash helmet. In non-lethal accidents the pulp helmets so alleviated the injury as to halve the incidence of admission to hospital.

To what extent the helmets were life-saving it was impossible to determine. After the crash helmet was made compulsory in the Army there was a considerable sustained fall in the total death rate of motor-cyclists in Britain (see Graph). But so many factors influenced the total death rate that it is impossible to estimate the effect of the helmets. The graph includes civilians as well as fighting Services. It shows the influence of weather, and of such events as the outbreak of war, preparations against German invasion, and final preparations for D Day. Doubtless, also, improved selection and training of Army motor-cyclists contributed to a considerable reduction in the total death rate from 1942 to the end of the war.

These monthly figures of the Ministry of War Transport would be greatly increased in value if they included figures of the number at risk, mileage, and petrol consumption.

Taking all the evidence into account the pulp helmet clearly affords remarkably good protection. The vulcanized rubber helmet is not so good: it is too brittle, and the slinging of the buffers is not sound. Our impression is that the steel crash helmet was also eventually good, but by that time we were too busy dealing with head wounds to collect observations. The leather helmet appeared to answer well for the N.F.S., whose motor-cycling was done in built-up areas and presumably at low speeds; but here again we have not had time to assemble the information which the N.F.S. kindly put at our disposal.

Crash Helmets for Other Purposes.—Other people, besides motor-cyclists are concerned with crash helmets—glider pilots, firemen, and miners, each with their own particular requirements, but space will not allow me to consider these.

Conclusions

From these experiences there can be little doubt that adoption of a crash helmet as standard wear by all civilian motor-cyclists would result in considerable saving of life, working time, and the time of the hospitals.

The present crash helmets could be considerably improved.

During the war much time was wasted by useful people searching for suitable buffering substances in place of rubber. Even when a material was in stock it could not be obtained because it was needed for other purposes more important in the war effort. Now that the war is over a much more efficient helmet could be manufactured at small cost.

As I said at the beginning, it is only by being in the Army Medical Services that we have been able to make these observations and, with the willing help of many people in different branches of the Service, to influence to some extent the loss of man-power from motor-cycling. Both in peace and in war, the Army Medical Services are in a unique position to make further contributions—in fact, to lead the country in prevention and alleviation of accidents, with considerable saving of their own man-power and their own Treasury grant. In peacetime they could, with the help of competent statisticians and physicists, carry out a programme of investigations on accidents which would be much more convincing and effective than anything we were able to do once war had begun, and which would keep the Army up to date in regard to supplies of protective equipment and ready for whatever might happen. In these days of war by mass production, once the war has begun the soldier's protective equipment cannot compete with demands for materials for offensive warfare.

Local education authorities have recently been reminded by the Ministry of Education that for maintained boarding special schools they have powers either to provide a store of clothing that can be lent to the children while they are pupils at the schools, or to provide as the child's personal property the clothing that he needs. In the case of schools not maintained by the authority a parent must not suffer financially because lack of a vacancy in a maintained special school compels him to send his child to a non-maintained school. Such pupils must also receive free medical treatment, including surgical operations, spectacles, hearing aids, etc.

PENICILLIN IN TREATMENT OF COMMON EXTERNAL EYE INFECTIONS

BY

JOSEPH MINTON, F.R.C.S.

Ophthalmic Surgeon, Hampstead General Hospital, and Queen's Hospital for Children, London; Assistant Ophthalmic Surgeon, West End Hospital for Nervous Diseases, London

The value of penicillin in the treatment of infections of the eyes was established in 1944 and 1945. Sorsby fully reported on the rapid cure of infants suffering from ophthalmia neonatorum when treated with penicillin drops. Rycroft, who had to deal with a large number of infected intraocular war injuries, treated his cases with penicillin given subconjunctivally or injected into the anterior or posterior chambers of the eye. Other observers reported on the value of penicillin drops, ointment, and lamellae in ocular infections, and on penicillin introduced into the eye by iontophoresis. The latter method of treatment has not been generally adopted.

This short paper gives an account of the use of penicillin for one year in the out-patient department of a children's hospital (Queen's Hospital for Children) and the ophthalmic department of a general hospital (Hampstead General Hospital). Penicillin was given to out-patients in these hospitals for use at home.

External Eye Infections in Children

The most common external eye infections seen in children are: (i) blepharitis; (ii) conjunctivitis, often associated with corneal ulcerations; and (iii) lacrimal sac infections. Mothers often bring infants, a few weeks old, who have suffered from a discharging eye since birth. Pressure on the lacrimal sac of the discharging eye will cause a profuse flow of pus from the lacrimal punctum, thus establishing the diagnosis of an infection of the lacrimal sac resulting from an obstruction of the lacrimal duct.

Other observers have now established that organisms causing the more common external eye infections (staphylococci, pneumococci, Morax-Axenfeld bacilli, etc.) are penicillin-sensitive. Conjunctivitis and blepharitis seen among children in London are in most cases due to a staphylococcal infection; it was therefore considered unnecessary to take swabs from the conjunctivae of the hundreds of children and infants treated in the casualty and the ophthalmic out-patient departments before penicillin was prescribed. All cases of blepharitis (ulcerative and squamous) and of conjunctivitis were treated for the past year with penicillin drops or ointment. Cases of corneal ulceration were also given atropine and hot steaming.

Blepharitis, which in the past so often resisted all forms of treatment, clears up quickly with penicillin ointment, but it very often recurs when treatment is stopped; the mothers are therefore advised to continue applying the ointment to the lids as a prophylactic twice a week for several weeks and to report at once if the condition recurs.

Conjunctivitis amongst infants and children also clears up within a few days when treated with penicillin. Penicillin drops (1,000 or 2,000 units per ml.) are given to the mothers in a bottle provided with a bakelite cap and a rubber washer; an eye dropper is fixed through an aperture in the bakelite cap. (The same type of bottle is used by the manufacturers of albucid eye drops.)

The mothers are told to keep the penicillin in the pantry (refrigerators do not exist in the patients' houses). Drops are to be used four times a day; at least three or four are to be instilled on each occasion. The bottle contains about half an ounce (14 ml.) of penicillin solution, which is sufficient for more than a week's treatment. The mother is asked to bring the child again a week later. In severe infections the penicillin is dispensed in the strength of 2,000 units per ml. In all other cases a strength of 1,000 units per ml. is ordered.

Lacrimal sac infections in infants take weeks, often months, to clear up. Penicillin drops—2,000 units per ml.—were used in 30 infants suffering from this condition. The drops were given to the mothers to be used, as in conjunctivitis cases, four times a day. The muco-purulent discharge ceased in most cases

after a week's treatment. In many cases the eye continued water. Penicillin was continued in these cases for three weeks. If at the end of that period watering had not ceased the lacrimal duct was probed under ethyl chloride general anaesthesia. Twelve cases out of the total of 30 had to be probed. The procedure takes only a few minutes, and one probing of an obstructed lacrimal duct in an infant suffices to cure the condition. Penicillin drops are ordered for another week after probing.

External Eye Infections in Adults

In the ophthalmic out-patient department of the Hampstead General Hospital very few children are seen. The most common external eye infections amongst adults are: (i) conjunctivitis and (ii) chronic blepharitis, which is usually of the seborrhoeic type with a secondary staphylococcal infection. It is often associated with seborrhoea capitis and infected seborrhoeic dermatitis of the external ear (auditory meatus) and of the skin behind the ear. (iii) Industrial eye injuries are also seen frequently, the common ones being corneal abrasions, corneal foreign bodies, and lime and cement burns of the conjunctiva and cornea. Lime burns are often severe in nature, and extensive corneal ulceration may follow, with pus in the anterior chamber (hypopyon ulcer). Patients suffering from lime burns are admitted to the hospital and are treated with penicillin drops (2,500 units per ml.) instilled into the eye every hour. Sulphonamides are administered by mouth, and, if the condition is severe, fever therapy (T.A.B. vaccine 0.1 or 0.2 ml. saline) is also given intravenously.

Conjunctivitis is not as common in adults as in children, and it is usually associated with ulceration of the cornea; the marginal corneal ulcer is the most common type. This infection is again largely caused by staphylococci and Morax-Axenfeld bacilli. These two organisms are penicillin-sensitive. Pneumococci and Koch-Weeks infections are seen less frequently—the pneumococcus is penicillin-sensitive. Koch-Weeks bacilli are only slightly penicillin-sensitive, but infections with these organisms are cured with penicillin in a concentration of 1,000 or 2,000 units per ml. Conjunctival swabs are therefore taken only in very severe and unusual cases; the majority of the out-patients were treated with gutt. penicillin 1:1,000 or 2,000 units per ml., given to them for treatment at home. The same instructions as to storing the penicillin in the pantry and not leaving the bottle of penicillin solution exposed to air are handed to patients. Drops are to be used four times a day. If the infection is severe an ounce (28 ml.) of penicillin is given for one week's treatment and the patient is told to instil six drops of penicillin on each occasion. All cases clear up very quickly. Patients suffering from corneal ulceration are given the same treatment, combined with atropine drops and hot steaming of the eye. They are instructed to return to the hospital every day, to be seen by the house-surgeon. Deep and extensive corneal ulcers are carbolicized—in most cases carbolicization is not necessary—and the ulcer shows signs of healing within a few days. Dendritic corneal ulcers which are due to a virus infection are resistant to penicillin treatment, and these ulcers are carbolicized and treated with gutt. albucid (sulphacetamide) 30%, atropine, and hot steaming of the eye.

Blepharitis, which, as already mentioned above, is most often of the seborrhoeic type, responds rapidly to penicillin treatment if secondary staphylococcal infection is present. The ulcerative type with red crusted lid margins is usually due to a secondary infection, and penicillin ointment is given to the patient to be used at home twice a day.

Allergic Skin Reactions due to Penicillin

A number of adults, after using penicillin drops or ointment returned to the hospital with a marked redness and oedema of the skin of the lids, often extending to the skin of the cheek and forehead. The condition cleared up within a few days when penicillin was stopped. These patients are allergic to penicillin and were suffering from a penicillin-produced allergic dermatitis. Skin-patch testing proved their sensitivity to penicillin.

These skin reactions to penicillin were not caused through the use of any particular fatty base in the penicillin ointment—they occurred also after the use of penicillin drops prepared by dissolving the drug in distilled water. Penicillin dermatitis

of the lids was seen among patients throughout the past year, and was not due to any particular batch of penicillin. Other observers also reported on these allergic skin reactions after the use of penicillin; but it is not yet established whether they are due to impurities which are still present in the penicillin supplied for general purposes. Pure white penicillin was not tried in these patients who were found to be penicillin-sensitive to the generally used yellowish preparation. I did not attempt to desensitize those of my patients who were penicillin-sensitive. In all such cases penicillin treatment must be discontinued.

It is worthy of note that none of the children treated with penicillin showed any allergic skin reactions.

Industrial Eye Injuries

Corneal abrasions, superficial burns of the cornea and conjunctiva, and patients who had corneal foreign bodies are best treated with gutt. penicillin. The drops are supplied to the patients for use at home. Three days' treatment usually suffices to heal the injured cornea and conjunctiva.

Potency and Stability

The life of penicillin in solution is limited. Penicillin is hydrolysed in the presence of moisture. The stability of penicillin is also greatly affected by the pH of the solution; the optimum pH is stated to be 6. Departure from this pH on either side leads to a considerable increase in the rate of deterioration. The rate of deterioration increases more rapidly on the acid side of pH 6, so that pH 6 to pH 6.5 is usually considered the best range. By interpolation, the rate of deterioration of a solution is twice as great at pH 7.5 and pH 5.2 as it is at pH 6. Temperature has a considerable effect on the stability of penicillin, the rate being approximately double for every 3° C. rise. Salts of certain metals destroy penicillin. The more important ones appear to be copper, lead, and mercury; iron also inactivates the substance. Oxidizing agents such as potassium permanganate and hydrogen peroxide will destroy penicillin, although the substance seems to stand up fairly well to reducing agents.

The actual life of penicillin in solution varies from batch to batch. Investigations carried out in the Glaxo Laboratories within the last twelve months have shown that the stability of the drug in solution is fairly high: even at room temperature its potency remained at between 90 and 100% for eight days. On the fourteenth day the potency of penicillin in solution kept at room temperature usually falls to about 75% of the original strength.

The pH of the solution has a much greater effect on the stability of the penicillin. Benedict and others have demonstrated that at pH 6 penicillin in solution remained stable for 360 hours, whilst at pH 5 (the acid side) and at pH 9 (the alkaline side) the stability lasted only 120 hours. In the preparation of drops and ointment for ophthalmic use it is essential to get the pH of these preparations as near as possible to the pH of tears. The pH of tears is 7.2. It is most fortunate that penicillin dissolved in distilled water has a pH between 6 and 6.5; such solutions are therefore not irritating to the eyes. Water not only inactivates penicillin but also provides a medium for the growth of penicillin-resistant organisms. These organisms produce penicillinase, which destroys penicillin. The drop-bottles must therefore be carefully sterilized.

Penicillin Eye Drops

At Queen's Hospital for Children the following method of preparation of penicillin eye drops is adopted. The drops contain 1,000 or 2,000 units per ml. in sterilized distilled water. 20 ml. of distilled water is poured into bottles fitted with a bakelite cap and rubber washer and then autoclaved at 10 lb. (4.5 kg.) pressure for half an hour. When penicillin drops are required two or four tablets of sodium penicillin (B. & W.), according to the strength required, are added to each 20 ml. The tablets supplied are of three different strengths—9,500, 10,000, and 10,500 units per tablet.

Penicillin Ointment

When penicillin ointment was first prepared for ophthalmic use "lanette" wax was employed as a base; but it was found

that the ointment was irritating to the eyes, as the pH of this fatty base is on the acid side and becomes more acid when the ointment is stored. "Lanette" wax was therefore discarded for ophthalmic use, and eucerin L.M. was found to be the best base for penicillin eye ointment. Within the first nine months the penicillin eye ointment was prepared with water; the penicillin was first dissolved in distilled water and then added to the eucerin L.M. At present water is not used in the making of ophthalmic ointment, and the stability of this preparation will therefore be very much greater. The penicillin is not soluble in the fatty base of the ointment, but it will dissolve in the tears fairly rapidly. When applied to the lids the moisture of the skin, and the tears which are constantly wetting the lid margins, will dissolve the penicillin. The delayed release of penicillin is advantageous in prolonging the action of penicillin.

The method of preparation of penicillin eye ointment as used at the Queen's Hospital for Children is given below.

The ointment is prepared in the strength of 400 units per gramme. 200,000 units of penicillin in powder form are rubbed down in a sterile mortar with a little sterile liquid paraffin. 500 g. of eucerin L.M. base (previously sterilized by heating in a sterotherm at 150° C.) are gradually incorporated. The ointment is transferred to sterile jars, using a sterile spatula.

The official B.P. method of preparing oculentum penicillin is as follows:

Penicillin (calcium salt)	100,000 units
Yellow soft paraffin	90 g.
Wool fat	10 g.

Melt together the yellow soft paraffin and the wool fat, filter while hot through coarse filter-paper placed in a heated funnel, and sterilize the mixture by heating at 150° C. for one hour. Place the penicillin (calcium salt) in a sterilized mortar and triturate with a small quantity of the basis until smooth; then incorporate the remainder of the basis gradually. Distribute into small sterile collapsible tubes and close.

The official B.P. oculentum has not yet been tried. It will be essential for the dispenser to obtain wool fat and paraffin molle in an anhydrous state. Samples of commercial wool fat and paraffin molle are known to contain varying amounts of moisture. It is also hoped that the ointment will retain a pH very near to 6 for a few weeks: a change to the acid side due to decomposition of the wool fat would destroy the penicillin. In the present state of our knowledge eucerin L.M. has the necessary requisites for an oculentum base: (i) it has very little moisture; and (ii) it does not turn acid and is considered by many pharmacists to be a superior base to wool fat in the preparation of oculentum penicillin.

Stability of Penicillin in Eye Drops and Ointment

To ascertain the stability of penicillin in the eye drops used at Queen's Hospital for Children, two bottles of eye drops as dispensed to out-patients were sent to Glaxo Laboratories. A

Graph showing the potency of penicillin eye drops; original potency, 2,000 units/ml. — = Refrigerator, ---- = Room temperature. This solution was exposed to the air on frequent occasions. (The apparent increase in potency is, of course, an assay error, the accuracy of the method being about $\pm 10\%$.)

biological assay was carried out. The deterioration of the penicillin in the eye drops at refrigerator and at room temperature is shown in the accompanying Graph.

The bottles were frequently opened and exposed to air in the same way as when the patients use them for treatment in their own homes. The solutions retained 50% of the original penicillin activity for about three weeks at room temperature, and

longer in the refrigerator. If one takes into account the undoubted fact that penicillin solutions, in the first place, are often of greater concentration than is therapeutically necessary, the useful life of the solution can be taken as being two to three weeks, and possibly longer. In one case the solution seems to have increased in strength. This, of course, is due to an assay error. The method of assay normally has a margin of error of plus or minus 10%, which is reasonable for any biological assay method.

The penicillin ointment was also sent to the Glaxo Laboratories for examination. The original pH of the ointment was 7.1, and this did not change significantly on standing. A biological assay on the ointment was not carried out. The penicillin ointment was prepared without water, and its stability at room temperature is probably that of the dry penicillin—this means that it will probably last longer than six weeks. The pH of the eye drops was 6.35, and this fell but very slightly.

These findings confirmed our clinical experience that the penicillin eye drops and ointment have an ideal pH value for ophthalmic use and are therefore not irritating to the eyes. They also confirmed that the excellent results obtained in the treatment of out-patients suffering from external infections of the eye were due to the high content of penicillin in the eye drops and ointment which were dispensed for use at home for one or two weeks.

Summary

Penicillin eye drops and ointment were used for one year at Queen's Hospital for Children and at the Hampstead General Hospital in the treatment of external eye infections. These preparations were given to the patients for use at home. The clinical results were excellent.

Allergic skin reactions of the lids and the skin of the face arising from the use of penicillin drops or ointment are described.

A biological assay of the penicillin eye drops proved that the content of penicillin when the eye drops are kept at room temperature, and with the bottles frequently opened and exposed to air, was 80% of its original potency at the end of fourteen days.

I wish to thank the Glaxo Laboratories for their great help, and particularly Dr. H. M. Walker and Mr. J. T. Marsh, M.P.S., who carried out the biological assay and gave me a great deal of useful information. My thanks are also due to Miss L. E. Jacob, M.P.S., the chief pharmacist at Queen's Hospital for Children, whose interest in this investigation enabled me to try various penicillin preparations.

1936) to certain cases of hypersomnia in which morbid hunger is exhibited during the attack, accompanied by motor unrest and mild confusion. In view of the rarity of the condition the following two examples are considered worthy of record.

Case I

Male aged 18, working as a milling operator. His previous health had been good, save for occasional attacks of bronchitis in winter. His mother (aged 50) and father (aged 52), one sister (aged 22) and two brothers (aged 26 and 22) were alive and well. One brother (aged 30) complained of attacks of sleepiness (noted at end of this case report).

History of Present Illness.—In 1939, at the age of 12, following an attack of "influenza" (then epidemic in the town in which he was living), he noticed a tendency to sleepy attacks at school. About the age of 14, when he started work as an office-boy, these attacks became pronounced. They occurred every three to six months and lasted from one to five days. During them he became very drowsy and would sleep if he closed his eyes. They occurred anywhere even at meals or when he was standing up. During the attack he was unusually irritable, difficult to rouse, and felt "confused and muddled" if he was roused. There was definite abnormal hunger but no excessive thirst. He experienced no physical discomfort and had no unusual thoughts or dreams. The attacks wore off gradually and for a day or two he felt somewhat "depressed and touchy." Sleep between the attacks was normal. Observers seeing him in an attack noted that the drowsiness came on usually in the morning and rapidly became severe; there was no abnormal behaviour, but he was slow to answer if roused and appeared "dazed." He was irritable, and when touched seemed to resent it intensely, throwing off the touching hand and contracting his muscles sharply. "He tended to curl himself up like a hedgehog." One attack had occurred during the "blitz" on Coventry in November, 1941, and he had "slept like a baby during the eleven hours that bombs were dropping." There were no hypnagogic hallucinations and no evidence of cataplexy or sleep paralysis. He had no other complaints, and lived a normal healthy life.

Physical Examination.—He appeared healthy. Speech was slow and deliberate, but there was no evidence of delayed cerebration or encephalitis. General physical examination revealed no abnormality in the nervous system, heart, chest, abdomen, or urinary system. Ophthalmoscopically the disks and fundi were clear. B.P. 122/80.

Special Examinations.—Urine acid; specific gravity 1012; no albumin or sugar present. R.B.C., 4,250,000 per c.mm.; W.B.C., 3,400 (polymorph leucocytes 40%, lymphocytes 57%, eosinophils 1%, hyaline cells 2%); haemoglobin, 90%. X-ray examination showed no abnormality of skull or pituitary fossa; a chest film revealed slight bronchial catarrh but no other abnormality. B.S.R. was 6 and 10 mm. at 1 and 2 hours. Blood Wassermann and Kahn tests negative. Lumbar puncture revealed a clear fluid with no increase in pressure. Examination of C.S.F.: Cells, 1 per ml.; protein, 20 mg./100 ml.; no excess of globulin; chlorides, 720 mg./100 ml.; sugar, 55 mg./100 ml.; culture remained sterile. Wassermann and Lange reactions negative. Electro-encephalography revealed no abnormality either at rest or during overbreathing. A fairly high potential alpha rhythm was noted in the occipital lobes.

Carbohydrate Metabolism.—A glucose tolerance curve gave figures of 66, 84, 105, 55, 63, 68 mg./100 ml. (fasting and at half-hourly intervals thereafter). On a low-carbohydrate diet (80 g. per day) he showed no abnormal response to exercise. An insulin tolerance test was carried out after a diet of 400 g. of carbohydrate had been given for three days, and following a fast of three hours (Fraser, 1938, 1941). After the administration of insulin the blood-sugar figures were 76, 32, 62, 64, 64, 74 mg./100 ml. (fasting and at 20, 30, 40, 60, 90 minutes thereafter). There was a slight fall in blood pressure and a feeling of hunger, but no other abnormal symptoms.

Progress.—While under observation an attack developed, the general features of which agreed with those described. The hypersomnia was well marked, and there was mild confusion with irritability accompanied by motor restlessness. The appetite was increased and could fairly be described as ravenous. There was no hypoglycaemia.

Investigation of the patient's brother, who complained of sleepiness, was also carried out. This revealed a picture of disturbance of sleep rhythm and features suggesting an encephalitis. The condition dated from an attack of "sunstroke" in 1955, and was not similar to that of Case I.

Case II

Male aged 29. His previous health had been good, save for occasional attacks of tonsillitis. His mother (aged 60) and father (aged 62), three brothers (aged 40, 36, and 30), and three sisters (aged 38, 35, and 33) were alive and well.

History of Present Illness.—In 1936, when aged 20, the patient developed attacks of drowsiness, sometimes coming on first thing

HYPERSOMNIA ASSOCIATED WITH ABNORMAL HUNGER: THE KLEINE-LEVIN SYNDROME

by

JAMES RONALD, M.D., F.R.C.P.E.

Junior Assistant Physician, Victoria Infirmary, Glasgow

Abnormalities of sleep are commonly considered as falling into two classes—narcolepsy (including sleep paralysis, cataplexy, and sleep hallucinosis) and hypersomnia. In hypersomnia the patient can be aroused with difficulty from the prolonged sleep. The pathology of the condition is obscure, and it may be associated with various pathological states, such as cerebral tumour, encephalitis, head injury, endocrine and metabolic upsets, and toxic or infective conditions of the nervous system. Attention has been called by Kleine (1925) and Levin (1929,

in the morning. Attacks lasted two to three days, and occurred at four-monthly intervals; and he could not identify any precipitating factor. He could be roused, but fell asleep again when left. He had not fallen asleep standing up, but while at work or while talking. He had excessive hunger but no thirst. There was no restlessness, but some confusion of thought with amnesia for events occurring during the sleepy period. Nocturnal sleep was unaffected. There were no unusual dreams or thoughts. Recovery took two to three days, during which time he felt rather depressed.

Physical Examination.—He appeared healthy. No evidence of encephalitis could be found. General systemic examination revealed no abnormality. B.P. 118/76. Ophthalmoscopic examination showed no lesion of disks or fundi.

Special Examinations.—Urine acid; specific gravity 1016; no albumin or sugar present. R.B.C., 4,860,000; W.B.C. (polymorph leucocytes 72%, lymphocytes 26%, eosinophils 1%, hyaline cells 1%), 7,200; haemoglobin, 94%. X-ray examination of skull, pituitary fossa, and chest showed no abnormality. B.S.R. was 4 and 7 mm. at 1 and 2 hours. Blood Wassermann and Kahn reactions negative. Lumbar puncture revealed a clear fluid with no increase in pressure. Examination of C.S.F.: Cells, 2 per ml.; protein, 30 mg./100 ml.; no excess of globulin; chlorides, 700 mg./100 ml.; sugar, 60 mg./100 ml.; culture remained sterile; Wassermann and Lange reactions negative. An electroencephalogram revealed no abnormality either at rest or on overbreathing.

Carbohydrate Metabolism.—A glucose tolerance test gave figures of 78, 110, 120, 100, 78, 70 mg./100 ml. (fasting and at half-hourly intervals thereafter). On a low-carbohydrate diet (80 g. per day) he showed no abnormal response to exercise. Following a diet of 400 g. carbohydrate for three days, an insulin tolerance test yielded these figures: 80, 52, 60, 66, 72, 78 mg./100 ml. glucose (fasting and at 20, 30, 40, 60, 90 minutes thereafter). There were no abnormal symptoms.

Discussion

The faculty of sleep is possessed by all living beings, and it has been suggested (Szymanski, 1918a, 1918b, 1920) that two types of sleep may be recognized—polyphasic and monophasic. The former is exhibited by animals, such as the rabbit, which depend on touch and smell for obtaining food, and the latter by animals, such as the dog, which depend on vision. The human being, initially polyphasic, becomes monophasic early in his development.

Pavlov (1927) has advanced the view that normal sleep represents a process of cerebral inhibition, but it must be recognized that other organs may be involved, as animals in which the cerebral hemispheres have been removed still show regular sleep and waking alternation (Best and Taylor, 1943). The existence of a "sleep centre" in the brain was first postulated by Dubois (1896) when he showed that disturbances of sleep were frequently associated with lesions of the nuclei of the anterior part of the aqueduct of Sylvius and the floor of the third ventricle. That the destruction of such a centre should be associated with hypersomnia, and not with insomnia, has not been explained. Rowe (1935) is of the opinion that the peri-aqueductal and periventricular grey matter should rather be regarded as a transmitting mechanism for sleep impulses passing between the cerebral nuclei and the autonomic nuclei of the midbrain. Demole (1927) has made the interesting observation that injection of solutions of calcium chloride in the region of the floor of the third ventricle produces deep sleep, the susceptible area extending from the lamina terminalis to the corpora mamillaria. Experimental work, borne out by clinical and pathological experience, implicates particularly the lateral hypothalamic areas in the region of the corpora mamillaria (Hess, 1932; Ranson, 1939). The work of Davison and Demuth (1945a, 1945b) suggests that the actual mechanisms concerned with afferent and efferent connexions are effected by means of the medial forebrain bundle (part of the hippocampohypothalamic tract), cortico-hypothalamic fibres between the hippocampus and the mamillary nuclei, and fibres connecting the cortex and hypothalamus through the inferior thalamic peduncle. It would thus appear that the production of normal sleep depends on the integrity of such connexions, and that lesions affecting them lead to disturbances of sleep. The subject has been reviewed by Kleitman (1939, 1944).

Of the abnormal forms of sleep, narcolepsy is more commonly encountered than hypersomnia. The association of morbid hunger with excessive somnolence is rare, but is well enough established to justify its consideration as a specific entity, differing from narcolepsy in the periodic

nature of the attacks, the absence of cataplexy and disordered nocturnal sleep, and the presence of abnormal hunger during the attacks.

The cases described above exhibit the typical features of the syndrome, which appears to be limited to males—onset in the second decade, appearance of attacks of abnormal sleep lasting several days, excessive hunger during such attacks, motor unrest, irritability, and mental confusion. Between the attacks the patients were both normal. In Case I the onset followed influenza, and a similar relationship has been noted by other writers. In neither case was there evidence of encephalitis or narcolepsy and its associated symptom-complexes. The response to sugar and insulin tolerance tests is considered to eliminate a diagnosis of hyperinsulism due to primary pancreatic over-activity, as judged by the standards laid down by Wilder (1940), and insulin intolerance was absent. An electroencephalogram revealed no abnormality, and this is in accordance with the findings of Critchley and Hoffman (1942). It is interesting to note that in a patient suffering from a hypothalamic tumour Walter *et al.* (1939) obtained an electroencephalogram resembling that found in deep, natural sleep.

The causation of the condition is obscure. Purves-Stewart (1937) considers that the symptoms are suggestive of exhaustion of the centres in the prefrontal lobe which not only control psychomotor activities but also influence gastro-intestinal motility. Excessive hunger has been noted by Fulton (1938) after extirpation of parts of the frontal lobes in monkeys; and intestinal hypermotility and restlessness by Messimy (1939). On the other hand, similar results have not followed frontal lobectomy in man. The somnolence is attributed by Levin to loss of function of the highest cerebral centres; that these do not all undergo inhibition at the same moment explains the variable time relation of symptoms. Critchley and Hoffman (1942), from their recent study of two cases, suggest that a patho-physiological process of undetermined nature affecting the hypothalamus is responsible, and do not consider the evidence in favour of a lesion of the frontal lobe to be convincing. The reversion to "polyphasic" sleep might be considered as supporting this hypothesis, and Lhermitte and Tournay's (1927) association of abnormal sleep with lesions of the hypothalamic region and third ventricle also bears it out.

A careful clinical study of the two cases here reported has failed to elucidate the problem of pathogenesis, and it is felt that until further evidence is forthcoming no definite conclusion can be reached.

Summary

Two cases of the Kleine-Levin syndrome (periodic somnolence, morbid hunger, motor unrest, and psychomotor upset) are reported. The mechanism of normal sleep and hypersomnia (excluding the narcolepsy symptom-complex) is briefly discussed.

It is pointed out that the present state of our knowledge of the condition is inadequate to determine accurately the pathological lesion, which may involve the prefrontal zone, the hypothalamic region, or both.

It is a pleasure to acknowledge my thanks to Dr. MacDonald Critchley for his advice.

THE XENOPUS PREGNANCY TEST

BY

R. F. MILTON, B.Sc., F.R.I.C.

The female toad *Xenopus laevis* was introduced into this country from South Africa in 1930 by Hogben for physiological purposes. It was subsequently shown that under natural conditions of existence this animal would not ovulate except upon stimulation by the male, and that if maintained under laboratory conditions out of contact with the male, oviposition would not normally occur. Hogben (1930), however, demonstrated that if the animal was injected with anterior pituitary hormone ovulation and oviposition could be induced. This fact was subsequently made use of by Bellerby (1934) and by Shapiro and Zwarenstein (1935), who independently suggested that the phenomenon could be utilized as a pregnancy test.

The procedure simply consists in injecting the urine (or an extract) into the dorsal sac of the toad and watching for the subsequent appearance of eggs. More prolonged experience with the test, as was reported by Elkan (1938), showed that it was at least as reliable as the Aschheim-Zondek method (Zondek 1931), and considerably more convenient.

As was emphasized by Landgrebe (1939) and later workers, the advantages of the test include: (1) its simplicity; (2) the objectivity (even when only a few ova extrude they are quite unmistakable); (3) the rapidity with which a result may be obtained (6-18 hours); (4) after a resting period of about three months the toads may be used again.

After the favourable comments on the test by Crew (1939) the toad method was introduced into the U.S.A. by Weisman and Coates (1941), who were much impressed by its simplicity and reliability. Weisman, Snyder, and Coates (1942) have since investigated the process on a much more quantitative basis, and have shown that the luteinizing factor gives a positive response at a much lower level than the follicular stimulating principle. Further work (Weisman and Coates, 1943) indicated that injection of about 100 i.u. of gonadotrophic substance represented the lowest level at which oviposition may be elicited. Since this amount is not likely to be present in normal urine, the likelihood of the test showing false positives is small.

It has been suggested, however, that as normally carried out the test is not sensitive enough to indicate pregnancies where oestrogenic excretion is low, as is often the case in the early stages of pregnancy.

This is partly because the amount of urine which may be injected into the animal is quite small, larger quantities having a lethal effect. In order to overcome this possibility, it is essential that concentration of the hormone from the urine be made before the test. The usual procedure is to treat the morning urine specimen with twice its volume of acetone, to separate by centrifuging, and to dissolve the hormone from the precipitate by shaking with a small volume of distilled water. In view of the low stability of the hormone in the presence of solvents this technique is fraught with some risk. Moreover, toxic substances are co-precipitated which, when dissolved and injected into the toad, often have fatal effects. In view of these facts other methods of separation of the hormone have been investigated.

More recent work by Katzman, Godfrid, Cain, and Dpisy (1943) has confirmed the observation of Lejwa (1932) that the gonadotrophic hormone may be separated in biological fluids by adsorption on permutit and elution with weak alkali. Katzman *et al.* use the permutit in the form of a chromatographic column and allow the urine to pass through at a steady rate so as to ensure complete adsorption. The urine is previously adjusted to pH 3.5, and since this is close to the isoelectric point of the hormone it is suggested that absorption rather than cation exchange with the permutit is responsible for the separation.

New Concentration Test

This method of separation and concentration has been found to be very suitable as a preliminary to xenopus tests, and does in fact provide a means of indicating the quantitative as well as the qualitative excretion of the hormone.

A chromatographic column is prepared quite conveniently from piece of glass tubing of bore approximately 1 in. (2.5 cm.) diameter and 15 in. (38 cm.) long, with a constriction in the bottom. A glass-wool plug is put in the constriction. The tube is placed in rubber bung, which fits in a Buchner filtration flask. Permutit "Decalco" brand (obtained from Messrs. Permutit, Ltd., Chiswick London) is then poured into the top of the tube until a column of the material about 10 in. (25 cm.) deep is produced. The column is then washed by pouring on dilute ammonia, dilute hydrochloric acid, and finally water. The column is dried by applying suction, and is then ready for use. The whole of the morning specimen of urine—e.g., 300 ml.—is filtered and adjusted to pH 3, with dilute acetic acid, using bromophenol blue as an external indicator. It is then transferred to a separating funnel and clamped above the column, and the tap of the funnel is opened to allow the urine to flow on to the column at a slow rate so that about 300 ml. is passed through in 30 minutes. Gentle suction is applied to assist if necessary. The column is washed with water until the washings are colourless, and finally sucked dry. Elution of the hormone is then carried out by pouring 10 ml. of 5% ammonia on to the column, and allowing it to percolate through before suction is applied, and is followed by a second elution with 5 ml. of dilute ammonia. (The column may be used over and over again if cleansing by acid washing followed by distilled water is made each time.) The eluates are then combined and aspirated to remove ammonia, and 5 ml. is injected into the dorsal lymph sac of each of three female *Xenopus laevis*. The toads are placed on wide-mesh platforms in jars, are just covered with water, and are put in a dark place (Weisman and Coates, 1944) for 18 hours. A positive qualitative result is evidenced by the appearance of eggs, ranging from a dozen or so up to hundreds.

Using this technique, a positive result may be obtained if the excretion of hormone is greater than about 500 i.u. a day—a condition which very rarely occurs in the absence of pregnancy, and usually is manifest after the first two weeks of pregnancy. Experience of this technique for the past year shows it to be extremely satisfactory. The quantitative test may be carried out by graduation of dosage and calculated on the basis of the Weisman findings.

I am indebted to Dr. C. J. O. Morris, of the Endocrine Unit, London Hospital, for criticism and for certain information with regard to the adsorption technique.

GIANT URETHRAL CALCULUS IN THE FEMALE

BY

NORMAN C. LAKE, M.D., M.S., D.Sc., F.R.C.S.

Senior Surgeon, Charing Cross Hospital

Urethral calculi are not common, and calculus in the female urethra may be regarded as rare, but when a stone reaches such a size that, having regard to the sex, it may be designated giant it is worthy of record.

The great majority of urethral calculi occur in the male and are usually associated with some pathological condition of the urethra, either present or pre-existing, such as stricture, periurethral abscess, etc., which may obstruct the voiding of a small vesical calculus or is productive of a stagnant pool of infected urine in which phosphatic stones are deposited. Like most stones which form in tubular structures, the initial shape is a spindle, but secondary changes in the surrounding urethra—periurethral pockets and so on—may lead to bizarre forms. Such stones have been reported of considerable size and have often been present for many years—in one case as long as 53 years.

In the female, however, the urethra is short and large in calibre; furthermore stricture is uncommon, and owing to vertical disposition stagnation of urine is almost unknown. For these reasons vesical calculi which pass the internal meatus will negotiate the rest of the urethra easily, while the formation of a stone *in situ* is unlikely. The great majority of the recorded cases of urethral calculus have thus been in the male.

The present case is that of a multiparous woman aged 60 who for over three years had complained of increasing discomfort and pain in the urethral region. For more than a year

FIG. 1.—Photograph of stone, showing shape and size.

there had been dysuria accompanied by a leaking incontinence; for the same period the patient had been unable to sit without pain, and so spent her time either standing or lying down. When she was first medically examined a large swelling was noted on the anterior vaginal wall, which was diagnosed as an abscess; in consequence antiphlogistic measures were instituted. After several months had passed the condition remained unaffected by treatment; it was then thought that post-inflammatory fibrosis might account for the swelling. As time went on, with increasing intensity of symptoms, the diagnosis was changed to one of probable malignant disease of the urethra, but some reluctance on the part of the patient

to submit to investigation and surgical treatment delayed further consideration of the case. After more than three years had elapsed since the onset, the symptoms reached such intensity and the discomfort became so unbearable that at last consent was given for further investigation. She was referred for an opinion whether any operative treatment was advisable or whether radium treatment should be adopted.

On examination she was found to have great difficulty in passing urine and yet to have a continual dribbling incontinence. In the anterior vaginal wall about an inch (2.5 cm.)

FIG. 2.—X-ray picture of stone after removal. Note the internal structure.

above the external meatus was a large (tangerine-orange) swelling, tender, red, and extremely hard to the touch; it was indeed thought to be too hard even for a carcinoma, and so suspicion of a calculus was raised, and confirmed both by x rays and by the passage of a probe, which grated against a stone about three-quarters of an inch (2 cm.) inside the rather pouting orifice. The stone was of such size that it seemed probable it had stretched the internal meatus, and fears were entertained that permanent incontinence might follow its removal. At operation the external meatus was first stretched as much as seemed safe, and was then incised backwards and upwards in the midline through the oedema-

tous anterior vaginal wall to the most prominent point of the swelling; this allowed the calculus to be gently detached and removed. Exploration now revealed that the internal meatus was intact and that the whole stone had lain within the tremendously distended urethra. The cone-shaped cavity was smooth-walled, except for a little inflammatory reaction, and no evidence of any diaphragm or atresia was discovered. Some catgut sutures closed the urethra down to the meatus again, a catheter being left *in situ* for a few days. After its removal it was, happily, found that a reasonable measure of control was present. This has slowly improved, leaving, nine months later, only a slight degree of stress incontinence under exceptional circumstances. As would be expected, there was a secondary cystitis present at first, which readily yielded to medicinal treatment.

The stone (Fig. 1) had a circumference of $4\frac{1}{2}$ in. (10.75 cm.) vertically, $3\frac{1}{2}$ in. (9.8 cm.) horizontally; length $1\frac{1}{2}$ in. (3.75 cm.), breadth $1\frac{1}{10}$ in. (3.3 cm.); its weight was 29 g. A scraping from the surface proved to be pure phosphate (except for a small amount of albuminous binding material), but the x-ray plate (Fig. 2) shows that the central nucleus is composed of denser material, possibly oxalate. The film also shows how the primary spindle-shaped calculus gradually conformed to the shape of the expanding urethra until it became an inverted cone with the point towards the external meatus. It will be noted that there was no evidence of any pre-existing pathological condition in the urethra, although such may have been present without causing symptoms, nor of any vesical calculus. It therefore remains an enigma how the stone formed and why it did not pass in its earlier stages.

Medical Memoranda

Surgical Treatment of Deformities of the Hallux by Skin-grafting

End-results of surgical treatment of such minor foot disabilities as ingrowing toe-nail, onychogryphosis, and subungual exostosis, when such results are obtained by the Jones radical treatment, have not always given the degree of aesthetic satisfaction anticipated. I would therefore like to outline the procedure successfully adopted in a field surgical unit among cases chosen at random, and at varying stages of chronicity and inflammatory reaction. The method features skin-grafting; and it aims at the final absence of shortening and of residual scar tissue.

Ingrowing Toe-nail

Under pentothal, gas and oxygen anaesthesia a tourniquet is applied round the base of the hallux; the nail is then avulsed and the whole matrix dissected out. In some cases it is necessary at the same time to do a bilateral wedge resection of the matrix, owing to the toe-nail deformity. The thigh is previously prepared for skin-grafting, and a small Thiersch graft the size of the nail bed is taken from the prepared area and transferred to the prepared nail bed. It is very important that a firm dressing be applied, and the following method was found to be the most satisfactory:

(a) A small firm compressed pad of sterile cotton-wool impregnated with petroleum jelly, the size of the graft, is pressed firmly down over the latter. This is surrounded by (b) a very thin layer of gauze wrung out of saline solution. (c) A thin layer of petroleum jelly is placed on top. The two layers of petroleum jelly keep the saline gauze moist. The whole hallux is then firmly strapped with "elastoplast." The patient remains in bed with a cradle over the leg, and sandbags on either side of the foot to prevent movement. On the fourth day the patient is taken to the theatre, and, with the strictest asepsis, the dressings are removed for inspection. Petroleum jelly gauze dressings are then reapplied and the patient is returned to bed until the seventh day, when the area is again inspected. From the seventh to the tenth day dry dressings only are necessary. Patients are allowed baths from the seventh day onwards before their dressings are reapplied. Cases dealt with in this manner were discharged from hospital on the eleventh day, with a perfectly sound result, and when seen three months later had had no trouble whatever. There were no complications in a total of nine cases, and all skin grafts had taken when the primary inspection was made. They were, with one exception, free from

infection when operated on; and a one-stage operation was undertaken.

In the infected case a two-stage operation was necessary. Under gas-oxygen anaesthesia complete avulsion of the nail and nail bed was carried out, and saline dressings were applied. Penicillin, 100,000 units, was given intramuscularly. The most suitable time for the second stage was assumed to be on the third day, when granulation tissue was beginning to form. Under gas-and-oxygen anaesthesia a Thiersch graft was taken from the previously prepared thigh and transferred to the field of operation. The dressing and post-operative management were similar to those of the uninfected cases, and the result was equally satisfactory.

Onychogryphosis.—Two cases of uninfected onychogryphosis were dealt with by skin-graft methods. In both it was necessary to do a wedge resection. The remainder of the operation, and the post-operative management, were as for ingrowing toe-nail. Both results were good.

Subungual Exostosis.—A one-stage operation is all that is necessary here. Once the exostosis has been removed, the procedure is the same as in the previously recorded conditions.

CONCLUSION

The use of skin-grafting when dealing surgically with such conditions as ingrowing toe-nails, onychogryphosis, and subungual exostosis assures a more effective and cosmetic result by obviating the necessity for suturing, with its resultant liability to contracture and scar deformity.

J. HUME STEWART, L.R.C.P.&S.Ed., L.R.F.P.S.G..

Graded Surgical Specialist.

Field Surgical Unit, B.A.O.R.

Rat Scratch causing Weil's Disease

Much has been published recently on cases of Weil's disease occurring among British troops in Italy and Normandy, but, so far as can be ascertained, infection was from bathing pools and rivers. Whereas several cases of Weil's disease have been diagnosed and notified in Cardiganshire during the last five or six years, this is the first case in that county where the source of infection could be traced to an actual rat scratch. The other interesting point about this case is that a clinical diagnosis of Weil's disease was made before the method of infection was discovered.

CASE RECORD

A farmer aged 24 was seen on March 16, 1946, complaining of headache, vomiting, generalized aches and pains, followed later by a rigor. The headache was acute frontal and retro-orbital in distribution, and there was also photophobia. The aches and pains were intense, confined to the back, the calf, and thigh muscles. The muscle pains were aggravated by movement. Vomiting was persistent for the first two or three days, and the vomit was bile-stained. On examination the temperature was 102° F. (38.9° C.), pulse 120, respirations 16. Examinations of abdomen, chest, central nervous system, and urine revealed nothing abnormal. The patient was kept under observation and symptomatic treatment given. Two days later there was still no change in the symptoms: muscle pains continued prominent, and vomiting was present. On examination the temperature was 100° F. (37.8° C.), and the pulse 120. Enlarged glands were palpable in both groins and axillae, and abdominally there was splenic tenderness, but neither spleen nor liver was palpable. Twenty-four hours later the patient was jaundiced, the jaundice of a more orange tint than the usual catarrhal variety. The conjunctivae were of course jaundiced, and there were moderate bilateral subconjunctival haemorrhages. There was also a mild bilateral blepharitis. The liver and spleen were palpable, and the urine contained large amounts of bile and albumin. The temperature was still 100° F., but the pulse rate had dropped to 100. There was a leucocytosis of 18,000, with 89% polymorphs. The red cell count was 4,250,000, with a haemoglobin of 75%. The blood pressure was 112/65. A diagnosis of Weil's disease was made, and 5 ml. of blood were taken for agglutination against *Leptospira icterohaemorrhagiae*. The report of the test was as follows: "His serum gives partial agglutination of a suspension of *L. icterohaemorrhagiae* at 1 in 10 dilution. Suggest that this test is repeated in seven days."

Fluids, glucose, and alkalis were pushed, and in another 24 hours vomiting abated, with a marked improvement in the patient's general condition. The urinary secretion was carefully observed and measured in order to ascertain the early presence, if any, of oliguria. At this stage the patient disclosed that on March 9 (one week before the start of his illness) a rat cornered by a dog in the stables darted up his trouser-leg before being killed. There had been a few small scratches on the inner aspect of his right thigh, which healed and disappeared within 48 hours.

From now on until March 30 the patient ran a fever of 99–100° F. (37.2–37.8° C.), and had marked albuminuria. His urinary output was, however, satisfactory (average, 42 oz. (1.2 litres) per 24 hours), and he was quite comfortable, with no further vomiting. On March 31 the jaundice was clearing, and there was only a trace of albumin in the urine. A further agglutination test on April 3 was positive, with agglutination in a dilution of 1 in 1,000. On April 7 he felt well, the jaundice had cleared, and his urine was albumin-free. Apart from the early conjunctival haemorrhages there were no other haemorrhagic signs, such as epistaxis. At no time were the liver and spleen noticeably enlarged.

Treatment consisted of massive doses of alkalis, a large fluid intake, and plenty of glucose. Penicillin was not used, as this seemed to be a fairly mild case of Weil's disease, and also it was understood that for favourable results penicillin therapy must begin early in the disease. The duration of illness was 24 days.

COMMENT

The case reported above is of Weil's disease occurring in an agricultural district of Wales following a rat scratch. In diagnosis of any condition in which there is a combination of pyrexia, jaundice, and albuminuria Weil's disease should be borne in mind. Although the duration of illness in this case was only 24 days, asthenia was marked, there being a loss of weight of 12 lb. (5.4 kg.). Vigorous action is now being taken by the local authorities to increase rat destruction.

We are indebted to Dr. Evan Evans, of Lampeter, for his helpful advice and co-operation, and to Dr. Suds, Emergency Public Health Laboratory, Aberystwyth, for the agglutination tests.

Recurrent Inguinal Hernia

No very recent figures are available as to frequency of recurrence, but the rate is probably still 5–10%. Many operations have been done in the last few years by young surgeons, who have not always removed the whole sac or the lax peritoneum which produces the direct element. Sometimes a hernia of the linea semilunaris is missed. Fascioplasty operations are not yet widely practised; insufficient attention is paid to closure of a wide internal abdominal ring; and, finally, the tone of the abdominal muscles is allowed to relax by too much rest in bed and lack of early exercises.

OPERATIVE TECHNIQUE

In dealing with a recurrent case, I proceed as though there had been no previous operation. Having exposed and lifted up the cord, holding it over to the outer side, I split the coverings on the inner aspect and define the circular fibres of the internal ring; these may be felt before they are seen. With a sweep of the finger round to the outer side the spermatic vessels and vas are identified. The peritoneum is then picked up and opened. If a sac has been left and is present in the cord, the finger is introduced and it is drawn up by gauze dissection without disturbing the structures of the cord. Attention is then directed to the removal of the slack peritoneum behind the epigastric and hypogastric arteries. This is pulled up and freed by gauze sponging until bladder fat is identified. The sac is clipped with large forceps and the peritoneum is stitched. The line of suture may be 3–4 in. (7.5–10 cm.) long, but it is reduced to a point by tying the two ends of the thread together. Examination of the inner aspect of the excised sac often reveals fibrous nodes, the "corns of Villandre."

Fascial Suture.—The assistant cuts a piece of fascia from the opposite thigh, 4 in. by 1 in. (10 by 2.5 cm.) wide, which makes four strips. The first one is used to close the abdominal ring; one end is anchored by a thread stitch, and the strip is passed through the ring fibres by my fascioplasty forceps. One of the stitches approximates the edges between the vas and the vessels—Torek's stitch. This strip is fastened off by a thread stitch. A flap is cut from the inner portion of the external oblique aponeurosis, base downwards, and is fastened across the floor of the canal, being stitched to Poupart's ligament and the conjoined tendon respectively. The cord is replaced and the roof restored by another fascial strip. I suture the deep layer of the superficial fascia separately before closing the skin.

After-treatment.—I consider it important to encourage the restoration of the tone of the abdominal muscles, and therefore start gentle exercises after 24 hours. The patient begins by tightening up his muscles once an hour, soon performing definite movements, such as sitting up. He is allowed out of bed on the fifth day, is walking on the tenth day, and is encouraged to go back to work after 28 days.

COMMENTS

If the surgeon finds the sac, excises it widely, and carries out a fascial repair, with the co-operation of the patient and early restoration of the muscle tone, there is very little chance of recurrence.

The commonest cause of recurrence is failure to identify and remove the sac. The importance of wide excision of all slack peritoneum has been emphasized.

Visiting Surgeon, Mayday Hospital, Croydon.

Reviews

LUPUS VULGARIS

The Problem of Lupus Vulgaris. By Robert Aitken, M.D., F.R.C.P.Ed. (Pp. 69; illustrated. 15s. plus 7d. postage.) Edinburgh: E. and S. Livingstone.

Though not a particularly common disease there is no doubt that lupus vulgaris, owing to its chronicity, its disfiguring effect in so many cases, and the length of time and the expense needed for its successful treatment, presents a serious problem the existence of which has been realized by several generations of dermatologists. The gravity of the situation is increased by the fact that for the most part lupus is a disease of the poorer sections of the population. For this reason the main burden of its treatment is bound to fall upon public authorities, and up to the present time they have been extremely reluctant to shoulder the load. Their backwardness is the less excusable because since the inauguration of light treatment by Finsen at the end of the nineteenth century, and particularly since the improvements on his original method introduced by his followers, the successful treatment of this disease has been for the most part simply a patient and prolonged application of the principles laid down by him.

Dr. Robert Aitken in the present volume once more points out the need for co-ordinated action between the medical profession and the public authorities. At the present time there are regrettably few centres in England or Scotland where the disease is properly treated, and even the law requiring the notification of all cases has been allowed to fall completely into abeyance. The regular notification of lupus vulgaris in daily practice would have at once the salutary effect of enabling an accurate estimate to be made of the numbers of lupus patients in existence and hence what provision is necessary for tackling the problem as a whole. Meanwhile those who are interested cannot do better than read Dr. Aitken's little book. In it he has condensed the experience of thirty years spent (though of course not exclusively) in the study of this subject. The late Sir Norman Walker, who wrote a paper on the "Need of Greater Method in the Treatment of Lupus," which he read at the Aberdeen meeting of the B.M.A. in 1914, inaugurated the modern regime of the treatment of lupus in Scotland. His efforts were temporarily frustrated by the war of 1914-18, but subsequently he opened a special lupus clinic at the Edinburgh Royal Infirmary and this received much-needed assistance from the light department which started in 1923. His mantle has fallen upon the shoulders of Dr. Aitken, and the results of his work are now before us. They are good, but, as he maintains, they might be much better with proper co-operation from the public authorities. The publication of this book is really a plea for that. It appears at a most opportune moment, for the whole medical service of Great Britain is now cast into the melting pot and the improved handling of the treatment of lupus is one of the things we may reasonably expect from the new era of medicine about to open. Dr. Aitken's book is perhaps primarily intended for the medical profession, but it should be studied even more carefully by all the non-medical administrators of the Ministry of Health and their satellites and also by our legislators.

SOCIAL PAEDIATRICS

Child and Adolescent Life in Health and Disease. A Study in Social Paediatrics. By W. S. Craig, M.D., F.R.C.P.Ed., F.R.S.Ed. Foreword by Charles McNeill, M.D., F.R.C.P. (Pp. 667; illustrated. 25s. plus 7d. postage.) Edinburgh: E. and S. Livingstone. 1946.

Prof. W. S. Craig has performed a service of national importance by compiling, after a long period of careful study, this excellent treatise giving a bird's-eye view of the whole field of paediatrics in so far as poor children are concerned; and if the adjective "poor" seems unsuitable at a time when economic circumstances are steadily becoming more level throughout the country, let us replace it by "less fortunate." And it is well to remember that the chief factor influencing the fortunes of childhood is the quality of the home. If all homes were as good as the best—using that word in the widest sense—Prof. Craig would have been able to cover the whole range of his

subject in a much smaller volume. The reader will note that he frequently refers to the influence of home conditions upon children, and he deals specifically, though briefly, with the subject on p. 245; perhaps if he had made a fuller reference he would have focused the reader's attention more sharply upon the most fundamental of a child's needs, namely a good home. This comment should not, however, be taken as any reflection upon the merits of this work. What Baedeker did for intelligent travellers, Craig has done for paediatricians and for all who have the welfare of children at heart. He has provided us with a map of the paediatric country, and a precise and comprehensive description of its features; and he has seized every opportunity to indicate, either directly or indirectly, the paths along which progress has been made in the past and the requirements for further advance.

Part 1 is a most interesting historical sketch describing the development of the many services now available for children—services which are remarkable alike in their number and in their lack of co-ordination. Part 2 describes the present provisions for the care of children; healthy school-children, sick children, delicate children, blind children, deaf children, epileptics, delinquents, the homeless—in fact, all children (except the very fortunate) are to be found in this procession as they run, skip, and alas sometimes stumble and falter pathetically through the pages. This is a truthful and objective summary, unspoilt by any empty emotionalism, and it will help to counteract the spirit of complacency which is still to be found all too frequently. The training of all those who participate in paediatric work is also described in this part of the book. Part 3 deals rather briefly with future developments; and Part 4 might be described as "potted Acts of Parliament," for it gives, in simple language, the essence from the paediatric point of view of the many enactments which have a bearing upon the subject. The volume concludes with several excellent appendices and a first-class index.

This is undoubtedly a most valuable work, which has been aptly described by Prof. Charles McNeill, in his thoughtful and stimulating foreword, as "immense both in its range and complexity; and no less in its importance." There are, as might be expected in the exposition of so great a mass of evidence, a few errors which can be corrected in future editions, but the work may be accepted as authoritative and it is warmly recommended as a well-written and reliable guide which stimulates while it teaches. An improved paediatric service is on its way, and both planners and practical workers in the service would do well to keep Prof. Craig's book beside them for frequent reference. The medical profession owes a great debt not only to the author, but to the publishers, whose work is well up to their usual high standard.

NEUROLOGY, PSYCHIATRY, ENDOCRINOLOGY

The 1945 Year Book of Neurology, Psychiatry and Endocrinology. Neurology, edited by Hans H. Reese, M.D., and Mabel G. Masten, M.D. Psychiatry, edited by Nolan D. C. Lewis, M.D. Endocrinology, edited by Elmer L. Sevringshans, M.D. (Pp. 720; illustrated. \$3.00 or 18s.) Chicago: The Year Book Publishers; London: H. K. Lewis and Co.

This book is always welcome because it gives abstracts, often with editorial comment, of the principal articles in the literature, foreign as well as American, in the three subjects. As might be expected many of these are related to war medicine and surgery but by no means exclusively so.

In the neurological section some interesting work on reflexes is covered, and head injuries, concussion, and tumours are discussed by many authorities. Some new work on epilepsy and the electroencephalogram is of considerable interest as are some observations on the demyelinating conditions. Peripheral neuritis and nerve injuries are fairly well covered and there are accounts of the so far disappointing results of penicillin in neurosyphilis. In the psychiatric section a good deal of work has been done on the electroencephalographic findings in various conditions, and some articles are included on shock therapy and leucotomy. There are several articles on the organic psychotic reactions and quite a number on psychosomatic conditions, and the final item reviews military psychiatry. In the endocrine section there are descriptions of recent work on the thyroid, and the account of experience in the use of thiouracil is of interest. The other glands are adequately dealt with in the various articles, but while knowledge continues to grow

it is obvious that there is much to be done before really adequate diagnosis and treatment can be achieved.

All doctors will find interest in this collection of abstracts, while specialists in the three fields should find it necessary to study the volume every year.

INDUSTRIAL MEDICINE

Medicine in Industry. By Bernhard J. Stern, Ph.D. (Pp. 209. \$1.50 or 8s. 6d.) New York: The Commonwealth Fund; London: Oxford University Press. 1946.

This book is issued under the auspices of the New York Academy of Medicine Committee on Medicine and the Changing Order. It is written by Dr. Bernhard J. Stern, a lecturer on sociology at Columbia University, and it traces in broad perspective the social, economic, legal, and professional setting within which industrial medicine has progressed. The book begins by giving a brief history of industrial medicine from the time of Hippocrates onwards, and then we read about the gradual rise of modern methods for the protection of the health and safety of the worker. The author is unduly critical in maintaining that Great Britain lagged in affording protection to workers, and was slow in adopting factory inspection and workmen's compensation, for he candidly admits that the U.S.A. was far behind our rate of advance in almost every particular.

In an interesting chapter on handicapped workers, evidence is adduced to show that the accident rate and absenteeism of the handicapped is lower than that of the able-bodied, while their production rate is higher. A long chapter on "Preventive Services" shows how different are the advantages provided in large plants as compared with most small ones. The average expenditure, in 1940, on a labour force of 49 million workers, was only 10 cents. The chapter on "Health Insurance" gives detailed evidence of the health plans adopted in some of the large plants, but it states that, taken together, the plans provide direct medical services to a negligible percentage of the total. The final chapter, on the industrial physician, maintains that the field of industrial medicine offers one of the most fruitful approaches to medicine and public health, and that it can play a preventive and curative part far beyond its present range.

Notes on Books

Xenopus Laevis: A Bibliography has been compiled by Drs. H. ZWARENSTEIN, N. SAPEIKA, and H. A. SHAPIRO, and is published for the University of Cape Town by the African Bookman at 10s., post free. Before 1933 experimental work on the South African clawed frog was confined almost exclusively to South Africa. Since the discovery that it could be used for the diagnosis of human pregnancy *Xenopus* has found an increasing use in all parts of the world. Hence a growing interest in the biology of this amphibian has arisen, and it has been extensively used as an experimental animal.

1. A full bibliography of the publications referring to it is given. A note on the pregnancy test, by R. F. Milton, appears at p. 328.

Preparations and Appliances

A RESISTANCE TYPE SKIN THERMOMETER

Dr. W. A. BOURNE, M.R.C.P., writes from Hove:

A new type of skin thermometer evolved at my suggestion by Mr. Arthur Light with advice from Prof. Paterson Ross has now been in use for some months at the Royal Sussex County Hospital, the Hove General Hospital, and in my private practice, and has proved consistent, robust, and as portable as a small mains wireless set.

The principle is that of an old, perhaps forgotten, friend, the Wheatstone bridge, the variable arms being a small metallic bead mounted for application to the patient's skin (Fig. 1, D), balanced against a potentiometer controlled by dial E. If these are not balanced there is a current across the bridge indicated by a meter F. The thermometer, run from electric mains through plug A, is brought into action by switch B, and monitor light G indicates that mains current is passing. For absolute readings some minutes are allowed for full stabilization. The needle of meter F will have moved from zero in a clockwise direction. On applying the alloy bead in its holder, the "skin probe" D,

to the skin, the needle F will be deflected according to the relation of resistances D and E. By moving dial E a point is found at which needle F shows a minimum deflection—i.e. is as far in an anti-clockwise direction as possible. It does not as a rule reach zero, but the end-point is sharp. Ten seconds are allowed for full stabilization, the temperature is read directly from the dial, and further readings can be made elsewhere at once.

FIG. 1

FIG. 2

The complete apparatus (Fig. 2) measures 9 in. × 9 in. × 11 in. (22.8 cm. × 22.8 cm. × 27.9 cm.), and has been used by the resident staff in a considerable number of cases with success after very brief demonstration.

I am indebted to Mr. Light, evolver of the apparatus, for the following technical details:

The thermometer measures skin temperatures to the order of $1/10^{\circ}$ Centigrade. The bridge method employed has many advantages, including freedom from ambient temperature change and from the necessity for initial setting-up operations. The heat-sensitive element, selected after investigation of many resistance materials which had usually the objection of large heat capacity for the required sensitivity, was an oxide alloy of maximum diameter 0.5 mm. sealed in a glass bead, which had a relation of heat sensitivity to heat capacity allowing overall stabilization time of "subject" temperature of 7 seconds. This was mounted in an electrically and thermally insulated holder suitably shaped for application to the patient's skin and giving necessary protection to the bead.

This "probe" is connected to the case containing the bridge network, precision potentiometer, controlled oscillator, and three-stage amplifier by a shielded concentric cable. The case itself is also shielded, and the apparatus is quite free from all electrical interference but most sensitive to temperature changes in the probe.

The bridge circuit is developed on conventional Wheatstone lines, care being taken to select low temperature coefficients for the stationary arms. One of the variable arms is of course the probe. The opposite arm is a precision potentiometer controlled from the front panel of the instrument. This is calibrated against known temperatures applied to the bead in stabilized copper-mercury cells. The full temperature range being determined by inter- and extrapolation. When all the arms of the bridge are of equal resistance there is no output from the bridge. Resistance changes in the patient's probe disturb the balance and produce a current voltage across the bridge. The resultant resistance change for a temperature change of $1/10^{\circ}$ being very small, a three-stage amplifier is added to make the null point of the bridge sensitive, and the final output of the amplifier led to a diode, the null point meter being connected in series with the load of the diode. To produce a minimum deflection on the meter again, the precision potentiometer is adjusted and the temperature read off directly from the 5 in. (12.7 cm.) dial fitted.

Temperature range $10^{\circ}\text{C. to } 40^{\circ}\text{C.}$ calibrated directly on dial with subdivision $1/5^{\circ}\text{C.}$ Probe capable of examining area down to 1 mm. diameter. Any number of probes can be fitted, and any length of lead used. Mains operated, A.C. or D.C., 200/250 volts. Finish—cream enamel cabinet. From Light Laboratories 31A, Shanklin Road, Brighton, 7.

"Tubarine" brand injection of *d*-tubocurarine chloride, the introduction of which is announced by Burroughs Wellcome and Co., is a stable solution of *d*-tubocurarine chloride containing 10 mg. per ml. for intravenous injection. It is intended for use as an adjunct to general anaesthesia, to promote muscular relaxation, and in conditions in which the action of curare is desired. As supplies are limited, it is available at present only in boxes of 6 ampoules, each containing 1.5 ml. (15 mg.). Further information is available on request from Burroughs Wellcome and Co., 12, Red Lion Square, London, W.C.1.

SEROUS PLEURAL EFFUSION

There is still difference of opinion on the prognosis and treatment of serous pleural effusions; the war has illustrated some of the difficulties of this. It seemed, for example, undesirable to send to the Middle East men having had a recent pleural effusion in the knowledge that they might break down with pulmonary tuberculosis; against this had to be weighed the possible loss to the Services of a highly trained man. And a man not allowed to go abroad on account of a history of pleural effusion might be deprived of his chance of promotion in his career. The only way of making a balanced decision is by a full knowledge of the facts. What is the evidence on the incidence of pulmonary tuberculosis after a primary serous pleural effusion?

These effusions may be considered in terms of three age groups—those occurring below 15, those between 15 and 40, and those over 40. Re-infection pulmonary tuberculosis is rare under the age of 15, and carcinoma of lung is a common cause of effusion over the age of 40. Investigations show that a primary tuberculous complex close to the periphery of the lung may give rise to effusion, and that in such cases the prognosis is more favourable in children than in adults. Graham¹ traced 39 out of 56 children with a history of primary pleural effusion and found 7 cases of pulmonary tuberculosis with 2 deaths; Smithers² followed up 32 cases out of a series of 49 and also found 7 cases of tuberculosis, 2 of which had proved fatal. Vaizey and Perry³ were able to trace 33 out of 60 after a period of five years or more, and found that only one had shown any manifestation of pulmonary tuberculosis. It is evident, therefore, that children with pleural effusion often do well and do not develop tuberculosis.

Several investigations to elucidate the prognosis have been made in adults, and many of the earlier ones, carried out before the advent of chest radiography, yielded results very similar to the more recent ones: an interesting commentary on the stethoscope versus x rays controversy. In 1846 Laennec⁴ taught—and indeed the whole French school did much to further the view—that pleurisy was often of tuberculous origin, while in 1897 Hamman⁵ showed that of 562 cases of pleural effusion 167 (30%)

developed tuberculosis. More recently two large series have been reported from Scandinavia. Borelius⁶ in 1932 followed up 230 patients for ten to twenty years and found that 23 had died of pulmonary tuberculosis, while there was a morbidity of 39.8%. Kallner⁷ in 1937 gave a detailed analysis of 690 cases which he followed up for periods up to twenty years: among these there was a mortality of 22% and a morbidity of 39%. In 1939 Trudeau⁸ reported the figures from the Saranac Lake Sanatorium. He divided his cases into those in which effusion complicated recognized pulmonary tuberculosis—a group which we are not here considering—and those apparently primary. In this second group there were 83 patients and 74 were well and working, 4 others were alive, and 5 had died. These figures were, however, based on a questionnaire issued to the patients and not on clinical or radiographical examination. Two surveys in England were interrupted by the outbreak of war in 1939. Vaizey and Perry³ followed up some 308 cases admitted to a general hospital in the ten years' period 1926 to 1936 and had succeeded in tracing 148, of whom 33 were under 15. Of the primary effusions between the ages of 15 and 25 there were 80 men and 57 women; 2 of the men and 1 of the women had died of pulmonary tuberculosis, 3 men and 4 women were found to have extensive pulmonary tuberculosis radiographed subsequently, while 24 men and 8 women showed no evidence of disease. They concluded that, in spite of many cases not traced, the incidence of subsequent tuberculosis could not have been less than 30%. Robson⁹ investigated those cases admitted to the Brompton Hospital between 5 and 12 years previously. He succeeded in tracing 70% of 111 cases and found a tuberculosis morbidity of 23%. It may be wondered if there is a selection in those admitted to a general hospital compared with a chest hospital.

Conybeare¹⁰ in a recent discussion considered a group of healthy young men who had developed primary effusions while on service in the R.A.F.; he had inquired into their subsequent history over a period of three years. He gave the tuberculosis morbidity rate as about 12%. This investigation, carried out in a way similar to Trudeau's, gives similar results and is open to the same objections. Brooks¹⁰ observed that in a similar investigation in the Royal Navy approximately 12% were found to have broken down with the disease and another 22% to have radiographical lesions in the lung.

All the evidence points therefore to an incidence of pulmonary tuberculosis of over 30% in persons developing a serous primary pleural effusion between the ages of 15 and 40. Arrangements ought, therefore, to be made for treatment with this knowledge in mind. The London County Council's arrangement of setting up a special sanatorium at Sidcup for the treatment of such cases might be followed by other authorities.

A DUTCH ABSTRACTING SERVICE IN ENGLISH

Many medical men in this country have received and are receiving invitations to join the Board of Editors of a medical abstracting service now being established in Holland. This service will issue a number of abstracting supplements in the various special branches of medicine on lines somewhat similar to those familiar to readers of the *Zentralblätter* previously brought out in Germany by the firm of Julius Springer. They will appear under the general title of *Excerpta Medica*. A distinguished group of Dutch medical men have associated themselves with this work, and we should have felt more able to extend a welcome to it were it not for two facts: the first is that the Dutch abstracting journals will be published in the English language; the second is that in ignorance of the Dutch venture the B.M.A. has established an abstracting service in the Editorial Department of this *Journal*.

That our Dutch colleagues have chosen the English language as their medium of communication is highly flattering to this country and a recognition of the possibility that English will replace German as the second language of medical men and men of science in Europe. It is, however, a matter of regret that before starting on this ambitious venture our Dutch colleagues did not first inquire whether any organization in Britain was not making a systematic attempt to fill the gap left in medical journalism by the disappearance of the *Zentralblätter*. It would have been considered unwise if we had thought of starting an abstracting service in German or French or Dutch without having previously inquired whether such a service was not likely to be introduced in the countries where these languages are native. However excellent may be the linguists at the disposal of our Dutch colleagues, it would seem unlikely that they will be able to provide medical readers in Europe with a version of the English language which comes up to the standards we try to maintain in British medical periodicals. Those familiar with articles in English appearing in foreign medical journals know well the obstacles that confront the translator. If, indeed, medical men in Europe and other countries are to regard Britain as a source of medical knowledge and an information service through the medium of English abstracts of world medical periodicals, then it is very much our concern that the English they read should be that in current usage in the country of its origin.

Apart from the important question of language, it is a pity that two competing abstracting services should be launched more or less at the same time. It is a pity because work will be duplicated where duplication should be unnecessary if the aims of the two services are similar. As there may be some misconception of the aims of the abstracting service now in operation in the Editorial Department of the *British Medical Journal* it is opportune to state again what they are. The immediate aim is to publish each month, beginning in January next year, two monthly abstracting journals—*Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics, and Gynaecology*. From these titles it should be clear that the scope of the journals is international—that is to say, we

shall include in the survey conducted through these two abstracting journals all the important medical journals published in the world, and these journals will subsequently be available in the Library of the B.M.A. In this way we hope to keep medical men here and abroad currently informed of medical work in progress in a world where, in spite of modern communications, doctors of different nationalities still know little enough of what is being thought and done outside their own frontiers. The publication of two monthly abstracting journals is not, however, the end-point of our abstracting service. Out of it it is hoped, will evolve a series of abstracting sections or supplements in the various specialties. These will be published in the first instance in relation to the quarterly journals published by the B.M.A. where the editors of these journals see the need for them and when more paper becomes available. It is hoped, too, to publish abstracting supplements in co-operation with the editors of other special journals published in this country. Our aim, in fact, is the same as that of our Dutch colleagues, and we differ only in the method of approach to the problem. In these days of increasing specialization we feel that it is more than ever necessary for the specialist to be aware of the problems workers in other special fields are tackling. Facts of science are being grouped in compartments that grow more and more watertight, and if the expert is to escape from the narrow confines of his own field he must be able to look over the hedge to get at least some idea of what the other man is up to. In medicine this is an urgent need and one which we are trying to meet.

To assist us in this task a few hundred medical men have already been asked to do the work of abstracting; and their response has been ready. At the same time our Dutch colleagues are inviting the English editors of their editorial board to send to Holland the names of suitable abstracters in the various specialties. The regrettable work of duplication has in fact started. It is not for us to suggest that medical men in this country should help to nourish a home-grown product, because medicine is international and knows no frontiers. It is, however, hoped that those wishing to support an abstracting service in the English language will carefully consider the problem before finally deciding which service is worthy of their support—the English or the Dutch. In an attempt to find a way out of the difficulty that has arisen we have suggested to our Dutch friends that they might consider publishing in their country a Dutch version of the two monthly abstracting journals which will be issued in January next year.

PLAN FOR WORLD FOOD BOARD

At the request of the Food and Agriculture Organization Sir John Boyd Orr, the Director-General, has prepared a report on long-term food problems for the consideration of the present conference at Copenhagen. There has never been enough food in the world to maintain normal health. Before the war more than half the world's population consumed daily less than the food equivalent of 2,250 calories, whereas in spite of the present shortage in the United Kingdom the average daily intake per person is 2,750 calories. Production of agricultural products will

ve to be doubled if all are to be relieved of hunger, provided with the basic necessity of good health, and enabled to live the 70 years that they may hope for: the average length of life is 30 to 40 years in many areas, but hardly 70 in the best-fed communities.

The rapidly increasing population in certain countries is an additional, though by no means insuperable, obstacle to any attempt at providing sufficient food for all; the main difficulty is the economic adjustment required to establish a continuous market with remunerative prices. Full employment with good wages would help to solve the problem of purchasing power in nations whose main industries are not food production; volume of trade and prosperity of agriculture are interdependent; but it is not easy to convince farmers who have seen prices for their products crash in times of glut that the danger of overproduction cannot arise in the immediate future. It is essential that increased food production should be the primary objective, but it is equally important that non-agricultural industries be re-established as soon as possible so that the purchasing power of countries in which these reponderate may suffice to cover the cost of food. A commendation characteristic of Sir John's humane approach to these problems is that countries in need of immediate assistance should be granted credits on approved programmes of development, which they would repay by the export of raw materials or other commodities, and that the financial worth of the borrower would not be the principal consideration.

The charter of the F.A.O. established it as a fact-finding and advisory body only, required to defer to national sovereignty, but the critical food situation last winter has compelled Sir John to go beyond these limitations. He proposes that a World Food Board should be set up with the functions of stabilizing (by the provision of funds if necessary) the prices of agricultural commodities, establishing a world food reserve with which to meet emergencies, and providing funds for financing the disposal of surplus food cheaply to countries that most urgently need it. The Board would co-operate with organizations concerned with international credits for industrial and agricultural development.

APPLIED RESPIRATORY PHYSIOLOGY

The physiology of respiratory function in health and disease is a promising field for investigation which has received too little attention in this country. One of the major problems of thoracic surgery is the selection of the right type of case for operation. A radical cure of the disease is of little use to the patient if the operation leaves him crippled by respiratory embarrassment. The assessment of a patient's respiratory function and probable reaction to surgical intervention often have to be made empirically; therefore any attempt to solve these problems scientifically must be welcomed.

A series of observations by Birath¹ on lung volume and ventilation efficiency are of interest in this connexion. The lung volume was determined, during quiet respiration, by a modification of the hydrogen-dilution method of van Slyke and Binger,² and it was found that in healthy subjects the residual capacity after maximal expiration did not exceed 35% of the total capacity. In untreated pulmonary tuberculosis the total capacity of the lungs was reduced, and here was an absolute increase in the residual capacity.

Three factors were responsible for these findings: compensatory emphysema, the presence of cavities increasing the pulmonary dead space, and a reflex rise in the respiratory level due to dyspnoea. Pneumothorax reduced the total capacity, as might be expected, but did not alter the relative proportions of its various fractions. Also the reduction of the lung volume was less than that of the insufflated air, a phenomenon previously observed by Christie³ and others. This discrepancy was not entirely accounted for by compensatory distension of the thorax, suggesting that there was a real increase in the volume of the uncollapsed lung tissue. After thoracoplasty the lung volume was reduced and the residual capacity increased, probably because fixation of the chest limited expiration. This defect remained for ten years after operation, although the total capacity improved. A similar defect was observed after pneumonectomy and lobectomy, but the distribution of the fractions became more normal with the passage of time.

Birath concludes that when part of a lung is put out of action there is an immediate increase in the volume of the remaining lung tissue, leading to distension of the functioning parenchyma. This is probably a reflex effect. Hess⁴ found that in animals a diminution of lung volume immediately produced an increased tonus in the diaphragm. This reflex has a double function: it increases the available alveolar surfaces, thus compensating for the reduction in gaseous exchange, and it opens up fresh capillaries to counteract the increased resistance in the pulmonary circulation. Birath thinks that the immediate action of this reflex accounts for the remarkable lack of functional disturbance which accompanies the removal of a lung. But a late effect of this distension is the production of permanent emphysema. In a subject who is already emphysematous, or whose lung capacity has been impaired by some other disease, such as tuberculosis, this defect may constitute a serious handicap after operation and may even prove fatal. Determination of the lung volume should therefore be of value when considering the indications for operation. If the residual capacity of the lungs is both absolutely and relatively too high, the probability of emphysema is great and respiratory function is certainly impaired. Estimation of the vital capacity alone is misleading in cases of emphysema; even when the functional capacity of the lungs is considerably diminished vital capacity readings as high as 3 to 4 litres may be obtained. It is to be hoped that further research along these lines will result in the development of a reliable method for assessing pulmonary function before embarking upon irreversible surgery.

NEW BLOOD

One of the minor compensations of the wartime paper shortage was the reduction in the output of ephemeral literature and the higher standard of editing of scientific journals. It seems doubtful whether this happy state of affairs will continue, for compulsory virtues are swiftly discarded. The end of the war has, in fact, seen the birth of a large family of new journals, the latest of which has the rather blunt title of *Blood*. This is a product of the American school of haematology, under the editorship of William Dameshek. It is printed on good paper, with occasional coloured plates and a blood-and-sand cover. The first number contains a review by Cohn of the chemical

¹ *Acta med. scand.*, 1944, Supplement 154.

² *J. exp. Med.*, 1923, 37, 457.

³ *Quart. J. Med.*, 1936, 29, 445.

⁴ *Die Regulierung der Atmung*, Leipzig, 1931.

components of the blood, followed by original articles, editorials, abstracts, and book reviews. Two of the diagrams are of the horoscopic type, much favoured by American authors, which are very mysterious to the casual reader. They are apparently prepared in an effort to display the author's whole knowledge of the subject in a microcosm, and they look more like problem pictures than visual aids to textual interpretation. "News and Views" has a slightly disturbing pan-American flavour, but we understand that in future there will be corresponding editors in Europe and Asia.

The danger which faces any specialist journal, and particularly one of haematology, is that it may become too precious. Haematology is not a unified subject or discipline in the same sense as neurology and cardiology, and it is too limited and depressing a section of clinical medicine and pathology to constitute a whole-time specialty. There is no agreement as to who should be its exponents, whether clinicians, pathologists, or transfusion officers, though Dameshek comes down, rightly as we think, on the side of the clinician. The most important causes of anaemia are malnutrition, malaria, and hookworm disease, none of which is likely to be adequately considered in a journal of haematology, while the study of leukaemia is a branch of cancer research. The great advances in haematology have not been made by professed haematologists, and future advances would be unlikely to be published in a journal of haematology. The scientist studying the Rh factor does not speak the same language as one who is studying the P.A. factor. The former is a geneticist and serologist, the latter a nutritionist and biochemist. Analysis of the chemical components of the plasma takes us into the field of large-scale chemistry and biophysics. The result of all this is that journals of haematology, such as *Folia Haematologica* and *Le Sang*, have often concerned themselves with the minutiae of the subject and have become the medium for long-winded and unimportant arguments among the *cognoscenti*. They have too often devoted their pages to articles on the classification of rare and inscrutable maladies or to dogmatic statements about the lineage of blood cells, unsupported by experiment or comparative pathology. The danger that Dr. Dameshek will have to avoid is that of having prepared just another dish of caviare instead of good solid meat. However, there probably is a place for a journal of this kind, just because the blood is the meeting-place of so many sciences, and we wish Dr. Dameshek good fortune in this task.

INTERNAL CAROTID SYNDROMES

The internal carotid artery represents the vertebrate "*arteria cranialis carotis*," which, with its fellow on the other side, serves to supply the whole of the mammalian cerebrum. In man it is connected with its mate by the anterior communicating artery, and posteriorly it joins up with a relatively recent arterial contribution by way of the vertebrals, basilar, and posterior cerebrals. Thus a *circulus arteriosus* is evolved, and in this way, too, the vascular supply of the brain is partitioned into two zones of influence, of which the anterior three-fourths forms the territory of the internal carotid artery. How much the posterior system owes to the carotid varies. This point is borne out by the variable calibre of the posterior communicating arteries, which are sometimes so large as to suggest that there may be an antero-posterior arterial flow within them. Arteriography has also shown that it is

possible to demonstrate the posterior cerebral ramifications by means of carotid injection in about 15% of all cases.

In morbid conditions the carotid is rarely the seat of vascular occlusion; the most usual cause for carotid syndromes is the deliberate surgical ligation of the artery. Untoward effects of this operation are an important practical problem, though luckily not a common one. Paralytic sequelae, which may come on immediately after carotid ligation or after a delay, were studied by Perthes and Brüning in 1926, and ten years later by Gollub¹. Three types are identified pathologically: (1) paralysis due to inadequacy of the collateral circulation; (2) hemiparesis from thrombosis or embolus formation; and (3) local cerebral oedema resulting from venous congestion. The second and the third may develop only after an interval, and only the third has a favourable outcome.

Schorstein's series² of 60 cases of carotid ligation for aneurysms showed a mortality of 13% and about the same proportion of neurological complications. His findings did not support the embolic theory, for he observed that the main cause of a hemiplegia was an inadequate circulation before operation. Poor health, anaemia, and a raised intracranial pressure are unfavourable circumstances, which add to the post-operative risk of cerebral anoxic necrosis and hemiplegia. In his view it is important that the patient should be nursed recumbent for three weeks after operation. Lambert Rogers³ believes that electroencephalography carried out at the time of temporary carotid occlusion is helpful in determining whether or not ligation will be followed by a dangerous degree of ischaemia. Another possible cause of dysfunction in the cerebral territory of the carotid can be seen in the angiospasm of traumatic origin—the so-called *stupeur artérielle*, or Kroh's spasm—due to a "near-miss" type of lesion. In Ecker's four cases⁴ war wounds of the neck or head produced a minor trauma of the internal carotid artery. Cerebral symptoms appeared within ten minutes. Oedema of the brain occurred early and lasted three or more days, the maximum swelling taking place within twenty-four hours. Narrowing of the cerebral arteries was actually demonstrated by arteriography, while air studies later revealed a dilatation of the ventricles, more especially on the homolateral side.

None of these authors mention the interesting clinical syndrome of "carotid hemiplegia." The association of optic atrophy on one side with hemiplegia and hemianaesthesia on the other forms a striking neurological picture (see Lestelle, *Thèse de Paris*, 1903). When the dominant half of the brain is involved there may result a severe aphasia of particular importance to those interested in speech affections because of the almost complete destruction of the zone of language.

The Home Secretary has appointed Dr. Robert Arthur Young to be a member of the Advisory Committee on the Administration of the Cruelty to Animals Act, 1876, in place of the late Sir E. Farquhar Buzzard.

The President of the Royal College of Physicians and the Master of the Society of Apothecaries of London have awarded the prize for the Joseph Rogers Essay (administered by the Society of Apothecaries) for 1946 to R. C. Wofinden (Rotherham), who submitted an essay under the nom-de-plume "Hygeia."

Correspondence

Keeping Mother and Baby Together

SIR,—It is with pleasure that we note that the committee of the British Paediatric Association whose preliminary report on "Cross-infection in Children's Wards" appeared in the *Journal* of May 4 (p. 673) advocates the above principle in future buildings. In our article on "Elimination of Cross-infection" (*British Medical Journal*, 1945, 1, 159) we gave a short account of our plastic surgery clinic for babies established on this principle. We have now been working under these conditions for nearly five years—i.e., giving each mother and baby a small room to themselves, with a window facing the sun, and still there has not been a single case of cross-infection—despite being very busy all the time. A few months ago a child soon after admission developed scarlet fever, and we realized that our system was to be tested. But by transferring mother and baby to our isolated room in the garden and adopting the usual precautions the infection did not spread, and operations went on as usual. Another child developed measles *three days after* returning home, yet no other case of measles developed in the clinic.

A necessary factor in the system is that the mother must be to a large extent a free agent. There must be certain rules and regulations of course, but to get a happy and contented baby one must have a happy and contented mother. A mother who is reduced to a nervous wreck by an autocratic ward sister will not serve the desired purpose, for the baby will also become discontented and miserable and therefore unresponsive to treatment. We contend that a baby and mother are a biological entity, and to get results must be treated as such.—We are, etc.,

Pleural Shock or Cerebral Air Embolism

SIR,—I should like to offer some criticism of Dr. D. Gutmann's letter on pleural shock (Aug. 24, p. 278). Although I do not deny the existence of pleural shock, I should like to point out how unconvincing are the three cases which he concludes to be due to this condition. He describes three incidents during needling of the chest, and I cannot agree from the evidence given that they were in fact due to pleural shock.

In his first and fatal case collapse occurred only after air had been introduced apparently into a pleural space. Necropsy rarely reveals the small quantity of air necessary to produce a fatal issue in such a case. In his second case, one of spontaneous pneumothorax having air withdrawn, there was already considerable circulatory and respiratory embarrassment before the insertion of the needle. The third incident, occurring in a woman with a ruptured lung abscess, might well be an example of vagal syncope, such as may attend any similar procedure in the sitting conscious patient, especially if seriously ill. Suturing a cut finger may have just such an effect in the normal adult.

As Dr. Gutmann states, serious collapse during the introduction of needles into the chest most commonly occurs if the lung substance is punctured or torn. This is surely because it is only if they enter the pulmonary circulation that small bubbles of air are likely to reach and block the cerebral or coronary vessels; and it is not, as Dr. Gutmann suggests, due to pleural shock. As pointed out in the *B.M.J.* (July 20, p. 94), relatively large volumes of air must enter the peripheral venous system to produce untoward effects, which are due to filling of the right ventricle with air. Small bubbles are harmlessly arrested in the lungs and absorbed. Moreover, as well-demonstrated at the operation of adhesion section, it is stimulation of the parietal pleura which causes pain, distress, and reflex phenomena. The viscus itself is relatively insensitive. If stimulation of the parietal pleura commonly caused pleural shock, a serious increase in the incidence might have been anticipated when the use of Morland's pneumothorax refill needles without local anaesthetic became widespread. In fact no such increase has occurred.

Air embolism occasionally causes collapse and death, and accordingly many suggestions have been made concerning precautions against its occurrence. The most fundamental of these is the proper use of the manometer. Some urge that the rubber tubing connecting the patient to the pneumothorax apparatus should be as short as possible and of small bore. Probably more important is the use of an efficient tap which allows no air to be delivered until turned on. The usual clip, so often faulty, is inadequate, and this probably explains many of the serious mishaps before the apparent introduction of air. Within a year I have witnessed three cases of collapse during thoracic puncture procedures.

Case 1.—A man of 40 years with a chronic secondarily infected empyema collapsed while having the empyema cavity irrigated. He remained unconscious for forty-eight hours. He was found to have a hemiplegia, which persisted until his death five weeks later. Necropsy revealed a parietal lobe abscess.

Case 2.—A man of 39 years, undergoing a pneumothorax refill in a recumbent position, complained of a tingling sensation in the right arm and lost consciousness for thirty seconds. The needle was immediately withdrawn, and although the manometric readings had been satisfactory on commencing the refill, lung puncture was evidenced by blood in the needle. Recovery was complete, although weakness of one arm persisted for two days.

Case 3.—A man of 32 years with a tuberculous empyema was undergoing aspiration, a procedure which he had several times previously endured. After the cannula had been in position for two to three minutes he became pale, complained of faintness, and lost consciousness. On being laid flat, the cannula still in position, he quickly recovered, and the aspiration was continued.

My interpretation of these events is as follows. The first was due to displacement of a septic thrombus in a pulmonary vein, with subsequent cerebral embolism. The second was an example of air embolism. The third could well be attributed to vagal syncope, and I see no reason to postulate pleural shock, as the occurrence seemed to have no direct relationship with either the insertion or continued presence of the cannula.—I am, etc.,

Aylesford.

A. P. BENTLEY

Autonomic Responses after Frontal Leucotomy

SIR,—It would appear from the contents of the annotation on "Autonomic Responses after Frontal Leucotomy" (Aug. 17, p. 234) that your writer's experience is of extensive cerebral incisions performed in a plane which is too posterior, as visualized by the resulting "placidity which has on occasion been compared to that of a vegetable." Presumably if one is to anticipate this degree of deterioration as the result of frontal leucotomy, an open operation (such as has already been performed by Lyster in America) is not a drawback. It would however seem to be a better aim to inflict the minimum amount of injury to both grey and white matter which is necessary to produce the desired result. We believe this minimum is far less than has so far been reported. Our incisions have always been made with a leucotome to avoid deterioration, and we have varied the fibres cut according to the symptoms; but we hope that a still smaller incision may eventually be found to suffice.

The other point in the annotation on which we would comment is the statement that the operation is a blind one and the surgeon is never entirely sure which tracts have been destroyed. In a recent paper (*Proc. roy. Soc. Med.*, June, 1946) we have shown how the operation need not be blind if a temporal approach is used and the Sylvian vessels are identified as a landmark; additionally, a method was described in the article whereby the extent and position of the incision in the white matter could be demonstrated on a tracing of a brain through the plane of section.

Lastly, another recent paper of Reiman's shows that the effects of section in certain cases may be obtained not by inducing placidity but activity. Thus we feel that though the annotation is useful in bringing this important work to a more general notice some of its value is destroyed by its contents.—We are, etc.,

E. CUNNINGHAM DAX.

Incubation Period in Infective Hepatitis

SIR,—The occurrence in June–Aug., 1945, of three cases of infective hepatitis at a European boys' boarding school during term-time, followed by a fourth case during the subsequent holidays, gives an indication of the probable incubation period. Details of the cases are not presented, but the three observed during the term all showed the cardinal features of anorexia, slight fever, and hepatic pain, followed by intense jaundice lasting for ten days or more. Blood smears examined for malarial parasites were negative in each of these three cases.

The first boy reported sick on June 23. The next two boys to be affected reported sick on July 18 and 19 respectively. A fourth boy began to suffer from anorexia on about Aug. 19 and was noticed to be jaundiced on Aug. 26. The second and third cases suggest an incubation period of 25–26 days, the fourth some 5 days longer.

A possible fallacy is the occurrence of subclinical cases. It may be noted that term ended on July 31, so that if the fourth boy acquired his infection while at the school the minimum incubation period, from a subclinical case, would have been 19 days. The second boy to be affected sat next but one to the first boy at meals, otherwise contact between the cases was only casual.

It is perhaps worth recording that there was an epidemic of measles in the school at the time. The occurrence of cases of infective hepatitis brought to an abrupt stop the collection and use of convalescent measles serum. None of the few recipients of the serum developed jaundice, however.

(This note is published at the suggestion of Dr. E. R. Cullinan and by permission of Hon. Director of Medical Services, Kenya).—I am, etc.,

Kenya.

FREDK. J. WRIGHT.

Early Treatment of Ocular Defects in Infants and Young Children

SIR,—I imagine that all ophthalmologists must deplore the delay which, not infrequently, they encounter in referring for a specialist's advice young children suffering from squint in particular, and also other ocular defects. The usual plea for delay is that the child is too young or that it will grow out of the defect. The truth is that the child is never too young and very rarely grows out of it; on the contrary it grows into it and a whole train of perversions arises. In this connexion I cannot do better than quote the late Bernard Chavasse:

"It seems probable that, if glasses were given to an infant immediately and as a matter of extreme urgency at the first momentary glide of the eye, the problem of accommodational squint, both in its visual and aesthetic aspects, would disappear. Operations would not be necessary. Multitudes of eyes would be saved for acute vision against the possible loss, by accident or case, of their fellows. A heavy burden would be lifted from community; and some very bitter waters would run sweet."

"If there is a squint the child pays with its sight for every day—whoever treats it. The child has a moral right to investigation and treatment. *It is the only way.*"

he delay of which I complain is not peculiar to this country, for Oscar Wilkinson of America in *Strabismus* (1943) complains just as strongly as Chavasse. If every general practitioner in this country reads this letter and acts upon it, a very great service will be rendered to the eyesight of the nation, and I say, deliberately, that I know of no other benefit which is so great and at the same time so readily available.—I am, etc.,

MAURICE C. MASON.

Physiology of Vision

SIR,—The *Journal* of April 27 has just reached me. I regret to find from it that Prof. H. Hartridge (p. 637) failed to point out to your readers the fact that Prof. Granit's work confirms my own views on the nature of colour vision which were first made public in my book, *A New Physiology of Sensation*.

In Lucknow, I may mention, first-year students were taught colour vision in their first term. It was not my custom, however, to lay out the different theories of colour vision for their inspection, as it were, and then attempt to make choice between

them. Instead, in addition to considering what electric currents do to that very abnormal cardiac preparation, the Stannius heart, they were also taught what the heart's natural stimulant, adrenaline, does to hearts. After that they were invited to consider what would happen if retinal end-organs were rhythmically active structures just as are hearts, and were stimulated to greater activity by the drug or hormone, visual purple modified by light.

Colour vision thereby becomes a matter of simple deduction, one no longer puts up some special adjustive theory to explain the phenomenon of complementary colours; one just predicts or deduces that such phenomena ought to be. My students further learnt that no theory of dark accommodation should be considered as acceptable unless one were able to predict from it the existence of complementary colours. I appreciate that to many of my contemporaries this is a hard saying, but I would even go further than this and claim that a valid theory of dark accommodation would automatically lead to an explanation of the colours of Benham's top.

I mention Benham's top because no satisfactory explanation of its colours was available until Dr. Naidu of Annamalai University took the matter up. In the "light" of orthodox theory he performed experiments over many months, and puzzled his brains to no result. Then he read my book and found an automatic explanation. His paper is published in *Current Science* (1938, 7, 273). Some day there should be more general appreciation of the point that there is unity behind the phenomena of vision, and that dark accommodation is even related to irritable weakness.—I am, etc.,

The Medical College, Rangoon.

W. BURRIDGE.

Migrainous Headaches

SIR,—In the interesting correspondence on the above subject, it has surprised me that no mention has been made of refractive errors, either as regards causation or treatment. Throughout fifty years of general practice I have never yet found a case which, if coming within the wide classification of migrainous states, has not had some refractive error or binocular imbalance—it may be slight or it may be gross. Having been suspected, the next step is successful correction, and here we are entirely in the hands of the oculist. He has to exercise his judgment as to how much to correct and how much to leave to the patient's own powers of adjustment.

Success is measured solely by the lessening and final disappearance of the migrainous symptoms. This latter result may come with dramatic suddenness. The symptoms may have been of a most varied character. The classical ones need no recounting, but unusual variants are, I venture to think, of interest. One patient told me, after the oculist had lessened her troubles, that in another part of the country she had escaped a cholecystectomy by the narrowest margin of time. Another elsewhere had been told that her only hope of relief from troublesome head symptoms was to undergo some cerebral operation, and that her vision was normal; but the discovery of astigmatism and its correction entirely relieved her. Another patient came from the Channel Islands on a visit to relatives some years ago, and when I called to see her I found her nearly unconscious and with a dusky blue colour. On inquiry I learned that attacks of this character came on about every three weeks. Headache and the other common symptoms played only a secondary part. The usual routine visceral examination revealed nothing abnormal, but the oculist found considerable hypermetropic astigmatism, which he corrected forthwith; and the family told me years later that not one attack occurred after she received her glasses. The case of another elderly lady illustrates the atypical nature of some migrainous conditions, in that her form of trouble was frequent falls followed by a dazed condition which had been diagnosed in the Midlands as petit mal. Again hypermetropic astigmatism was present, and the oculist's prescription entirely removed the trouble.

The above cases are only a few out of many, and I confess to the belief that every case approaching or resembling a migrainous state should be at all events suspected of refractive error or a "phoria"; and if present, there is, in my opinion, every prospect that a correction may ameliorate if not cure it.—I am, etc.,

Southsea.

M. ASTON KEY.

Penicillin Ointment

SIR,—We read Dr. I. Lloyd Johnstone's article (Aug. 10, p. 201), with much interest, and find it a very useful contribution towards the use of penicillin in eye cases. There are, however, some points where we should like to add our reflections based on nineteen months' experimenting at the Eye Department of the Caernarvonshire and Anglesey Infirmary, Bangor, North Wales.

Dr. Johnstone questions the reliability of collapsible lead tubes in dispensing creams. We have not had any trouble with them, and the cream dispensed in them did not deteriorate faster than that kept in glass containers. We repeatedly tested them against Oxford Standard staphylococci, and more recently against various organisms cultured from conjunctival sacs—*Staph. pyogenes*, *pneumococci*, etc.—and found that the zone of inhibition—taking an average—was 15 to 16 mm. when fresh, 11 to 12 mm. after one week's use by the patient, 9 to 11 mm. after two weeks', and 7 to 8 mm. after 3 weeks' use. Our cream contains 250 units per gramme. The nozzleed applicator tubes are the best containers for dispensing the creams: they give no trouble to the patient, and he need not observe sterile precautions.

With regard to the pH of the creams, our experience concurs with that of Dr. Johnstone. We find 7.2 optimal. As a base, we first used 30% lanette wax in water, but several patients complained of this being irritating. We then tried eucerine L.M., and are now using an equal mixture of the two. This is easily applicable, not too hard, and does not irritate the conjunctiva.—We are, etc.,

T. G. WYNN PARRY.
G. C. LASZLO.

Bangor.

Peptic Ulcer

SIR,—The paper entitled "A Study of Peptic Ulcer" by Drs. Hugh Gainsborough and Eliot Slater (Aug. 24, p. 253) tempts me to record an observation of my own on the physical characteristics of peptic-ulcer patients.

In the course of operating on some hundreds of cases of perforated ulcers I have been impressed by the very high proportion of the patients who had dark hair. Unfortunately I have no precise figures to quote, but for some years I have been in the habit of offering a modest financial reward of sixpence to my house-surgeons for each fair-haired patient with a perforated ulcer whom they could bring to my notice. Very few have been able to enrich themselves by a single sixpence at my expense, and none had previously heard of the association of this particular type with perforated ulcers. This leads me to suppose that the association, if generally recognized, is not commonly taught. The observation is of some practical value in that it indicates that the diagnosis of "perforated ulcer" in a fair-haired patient needs to be scrutinized with more than ordinary scepticism.

I would be interested to have the opinion of some of your readers, versed in anthropology and psychology, as to what light, if any, this observation may shed on the aetiology of peptic ulcer or on the factors which lead to perforation.—I am, etc.,

Edzwane.

FRANK FORTY.

Transmesenteric Hernia

SIR,—Reports of cases of transmesenteric hernia appeared in the *Journal* of Feb. 16 (Peter Martin, p. 238) and March 2 (James Moroney, p. 329) of this year. My return to England has delayed these reaching me, but it is evidently worth recording a further case of this rare condition.

On Jan. 21 a male African (Muganda) aged about 30 years was admitted to hospital, complaining of severe abdominal pain. The pain had woken him up about 2 o'clock that morning, and there was no relevant previous history. He vomited on admission, but his general condition was good; on examination of the abdomen nothing abnormal was found except a little tenderness below the umbilicus. An enema produced a constipated result, and the pain went off, but later in the day the pain increased again, abdominal distension was noted, and his condition began to deteriorate.

Laparotomy was performed about 20 hours after the onset of pain. It was found that about 12 in. of sigmoid colon together with 6 in. of lower ileum had herniated through and become strangulated in a foramen in the mesentery of the small intestine. But not only were the herniated coils of intestine practically gangrenous, the coil of small intestine was part of some 6 ft. of terminal ileum

which was also gangrenous. The foramen was situated at the base of the mesentery near the caecum, and was about 1/2 in. in diameter; it had smooth sharp edges. The affected ileum was resected with ileostomy, and the sigmoid marsupialized; but the patient died the next day.

In the article on transmesenteric hernia mentioned by Martin (Cutler, C. D., and Scott, H. W., *Surg. Gynec. Obstet.*, 1944, 79, 509) reference is made to 54 cases of this condition at all ages, with a mortality of about one in three. The history in all cases is similar, and exact pre-operative diagnosis is rarely possible, but the onset of gangrene is rapid. The site of the mesenteric defect is commonly much the same as in the present case; evidence is adduced in favour of its being due to a developmental defect in a relatively avascular part of the mesentery. It has been described as an incidental finding in 3 of a series of 1,660 necropsies. The incarcerated bowel is, in most cases, the small intestine, though one other instance in which it is the large intestine is reported; there is no reference to a case in which both large and small intestines are involved. That the sigmoid colon should pass from above downwards through the mesentery in the right iliac fossa is an interesting sidelight on the mobility of the intestines. Another extraordinary feature in the present account is that, as in Moroney's case, gangrenous gut was present on both sides of the mesenteric defect; there was no evidence of constriction at either end of the affected ileum, a central loop of which only was strangulated. It would appear that the blood supply of the whole segment had been interfered with in the mesentery, but it was not possible to ascertain how this had happened.—I am, etc.,

R. B. LEECH,

Mengo Hospital, Kampala, Uganda.

Church Missionary Society.

Rubella in Pregnancy

SIR,—I have read the correspondence about rubella with interest and feel that this personal experience may be of interest too. During the early part of 1940 I was seeing many cases of rubella but did not develop the complaint myself until about six weeks after seeing the first cases. I was then three months pregnant (second pregnancy). The disease lasted for three days with much sneezing and temperature of 100° F. (37.8° C.). For the subsequent four days I had considerable pain in my wrists. Four weeks afterwards a pilonidal cyst which had been quiescent for eight years became enlarged and infected and was dissected out under pentothal, gas, and ether anaesthesia, recovery being uneventful.

I had a female child of 5 lb. (2.2 kg.) three weeks after term. The baby suffered from mild neonatal jaundice and was a very slow feeder. Later she was amyotonic, extremities were blue, and the fontanelle bulging. There was frequent crying of "meningeal" type. She died at seven months from pneumococcal meningitis in spite of full dosage by mouth of sulphapyridine. Sight and hearing seemed quite normal and there was no congenital cardiac defect.

During the course of my work I have come across one case of congenital nerve deafness and aphasia in a girl of five whose mother gives a history of having had rubella at the seventh month of her pregnancy. In view of the data already collected of the effect of rubella on foetal tissues it would be a wise measure to warn those in charge of antenatal care to guard expectant women from this infectious complaint as much as possible.—I am, etc.,

"A WOMAN DOCTOR."

Immunization with B.C.G.

SIR,—The decision by the Ministry of Health to give B.C.G. a trial in this country will be welcome news to all doctors who are interested in the prevention and control of tuberculosis. The Minister is to be congratulated on this announcement.

This treatment, as far as reports show, has proved to be of great value in other countries. If it is found to protect children from tuberculosis it should prevent tuberculous meningitis in children, and later all those cases of surgical tuberculosis, whether of bovine or human origin.

Since I worked at the Pasteur Institute under Calmette and Guérin over some fifteen years ago I have been anxious to see B.C.G. tried out in this country and so far have been able to get nothing done.—I am, etc.,

HORHAM.

SYDNEY GORDON TIPPETT.

Trilene

SIR,—In reply to Dr. Walter Calvert (Aug. 3, p. 172), concerning amnesia following upon the use of trilene in midwifery, apologies are due to Dr. Calvert for overlooking his article, which we have now read. His apparatus would appear very useful, particularly as at the present day it is difficult or impossible to buy a Clover's inhaler. We look forward to the forthcoming communication promised by him.

Replying to Dr. T. D. Culbert (Aug. 10, p. 210), on physiological grounds alone we must agree to the contention that variation of the rate and depth of respiration must also vary the amount of available anaesthetic agent. However, we fail to see how this can be done with any degree of accuracy without a metronome and some method of measuring the depth of respiration, also a very co-operative patient. This would appear to be an expedient to remedy a defect rather than an equivalent method, and we would still prefer the simple accuracy of a variable administrator.

Referring to the point raised concerning anaesthesia, as opposed to analgesia, with trilene: the article in question only mentions narcosis up to the point of automatic breathing with use of the Clover inhaler and bag, followed by its removal and maintenance of light anaesthesia with the "open" inhaler set at 4/4 aperture. We have on occasions pushed anaesthesia to a deeper plane, and have noted the tachypnoea and tendency to cyanosis in certain cases. We have preferred, except in cases requiring the lightest plane of anaesthesia, to change to "open" ether, for which the trilene prepares the patient in a most excellent manner. The "open" Clover inhaler set at 4/4 aperture has been found to give after three to four minutes' administration adequate narcosis for the purpose of simple perineal repair. We thank Dr. Culbert for his kindly criticism and commendation.—We are, etc.,

Leeds.

"Drug Eruption" following Sodium Pentothal

SIR,—In view of the recent correspondence describing drug eruptions after the use of sodium pentothal an account of the following case may be of interest.

In 1941 an airman in the Middle East received a bullet wound of the perineum. Since then he has had about forty anaesthetics in the Middle East and in this country, being given pentothal or pentothal supplemented by an inhalation anaesthetic.

He was admitted to this unit in 1944 for repair, and in two years has had three operations under gas-oxygen-ether with a pentothal induction. In March, 1946, he came in with a blocked suprapubic catheter, which was changed under pentothal anaesthesia, using, in all, 20 ml. of a 5% solution (10 ml. for induction and 10 ml. intermittently). On his way back to the ward he developed an urticarial rash on his face, arms, and trunk, with gross swelling of his eyelids and lips. He was given adrenaline subcutaneously, 5, 10, 15, and 20 minims (0.3, 0.6, 0.9, and 1.2 ml.) at five-minute intervals, after which the rash subsided; and the patient was subsequently quite well. He was admitted again with a blocked catheter in June, but this time was given gas-oxygen-trilene without any rash developing.

On Aug. 1 he underwent an operation for the repair of a urethral fistula, and anaesthesia was induced with 10 ml. of a 5% solution of sodium pentothal, followed by endotracheal gas-oxygen-ether. The operation lasted fifty minutes, and neither during nor after the operation did a rash develop.

An intra-dermal skin test (2 minims (0.12 ml.) of a 2½% solution), using myself as a control, produced a skin wheal an inch in diameter with a surrounding flare. This developed in fifteen minutes, and took an hour to disappear. The patient is an otherwise healthy man of twenty-four who gives no other history of an urticarial eruption.

There seem to be two possible explanations for this case: first, that the patient has some degree of sensitivity to sodium pentothal, but that a dose larger than half a gramme is needed to produce a general reaction; and secondly, that this reaction is inhibited by the addition of an inhalation anaesthetic. Unfortunately there is no record of the amount of pentothal used in operations before he came to this unit.

It would be interesting to know if others have had similar cases and to hear their views on the variability of the reaction to this drug where sensitivity is known to exist.

My thanks are due to Mr. R. Mowlem, Mr. J. N. Barron, and Dr. H. Woodfield-Davies for permission to publish this case.—I am, etc.,

St. Albans.

P. H. MOORE.

Catheter and Prostate

SIR,—In 1934 my article "Complete Closure of the Blad in Cystotomy Cases" with special reference to prostatectomy was published in the *Lancet*. Practically all the methods now used by Mr. Wilson Hey, as described in his article in *Journal* of May 18, 1946, were suggested in my article with the recent advantages of chemotherapy. My article was originally submitted to the *B.M.J.* in the later part of 1932, but was not returned to me for over a year. As a result of this I lost priority of an operation for complete closure of the bladder in prostatectomy, as Harris's operation gained months' priority.

I did not persist with my operation after six operations because it produced so many heartaches due to catheter blockage, urethritis, and troublesome post-operative nursing. Mr. Wilson Hey's improved technique upon my original operation encourages me to try it again. His method of excising part of the trigone, so as to make the residual prostatic pouch a bladder one, diathermic haemostasis, anti-clotting with sodium citrate, and pre-operative and post-operative chemotherapy seem most logical. I would like to know the percentage cases in Mr. Wilson Hey's series; how many developed post-operative retention, and if any required bladder drainage.

Mr. Terence Millin's operation is a brilliant contribution to prostatectomy, and should replace all other methods, provided post-operative stricture does not become its bugbear.—I am, etc.

MORTON WHITBY.

Health Service Bill

SIR,—There has been some talk in these columns about "the issues not being clear" in our dealings with the Minister regarding the new National Health Service. To my mind there are enough points already on which agreement has been reached by the majority to make it possible to form a reasonably clear picture of our position.

As I see it these are the main points: (1) The majority (doctors and laymen) want a National Health Service. (2) The Government scheme is not a unified service. (3) The majority of the medical profession object to direction, negative or otherwise, and consider it unnecessary to secure proper distribution. They feel sure that adjustment of remuneration to make unattractive areas more remunerative would solve the problem. (4) The majority agree that payment by capitation fee and adequate mileage is the best scheme devised up to date. (5) A majority of practitioners object to their practices being bought by the Minister of Health without prospect of payment until retirement or death. (6) The majority object to the obvious infringement of their civil right to appeal to the High Court in the event of dismissal. (7) The majority object to the Minister's high-handed action in presenting us with a *fait accompli* each time negotiations are suggested.

Surely it is obvious by now that he has no intention of meeting any of our suggestions. What would any other group in the country do?—decline to work the scheme until their reasonable demands had been met, and so clarify the position now before any more time had been wasted. No other section of the community is in such a favourable position to withstand this bureaucratic domination. The Minister has said he cannot work the scheme without the co-operation of the doctors. Let him understand now and in no uncertain voice that doctors will not work the scheme without mutual co-operation from him. Bullying and issuing orders are not co-operation.—I am, etc.,

Birmingham.

W. MORISON.

SIR,—It has always been said that doctors are notoriously bad business men, and this may well indeed be true. But even the most irredeemable moron never yet entered into a contract without first knowing (a) what was expected of him, and (b) what he was to receive out of it. But that is precisely what we doctors are in great danger of doing if we allow this proposed referendum or plebiscite to be completed before we are in possession of more facts as to the terms of service under the new Bill. Dress up the referendum with whatever words you will, it still stands naked as the simple question: "Are you

Fine silver is distinguished by the device it bears—the Hall-mark. In the world of medicine the name of The Crookes Laboratories Limited denotes preparations of . . .

Unquestioned Merit...

Collosol Argentum, a stable colloidal suspension of silver, has established itself as a product of importance in the treatment of chronic and acute inflammatory conditions, particularly of the eye, ear, nose and throat.

Its properties as a silver preparation are unique : in addition to its stability it is non-irritant and non-staining and is entirely harmless to epithelial tissues.

Its beneficial effects are, therefore, not offset by any damage to, or impairment of, natural defensive mechanisms. In the eye it can be applied frequently, *i.e.* every hour, with results which often surpass those obtainable by the use of stronger preparations. For naso-pharyngeal use it is best used as a spray.

PARK ROYAL LONDON, N.W.10

SPENCER INDIVIDUALLY DESIGNED SPINAL SUPPORTS

**Spencer Designers make positive support
embodying comfort without undue weight**

Patient with fixed kyphosis wearing a Spencer Spiral jacket designed especially for her

For spinal curvatures, injuries, or disease, Spencer Designers create a spinal support that orthopaedic opinion finds most effective. It provides positive support with less weight and more comfort than does a brace.

The Spencer Spinal Support is designed to exert the degree of hyperextension or flexion of the spine required by the surgeon for treatment of the condition in the individual patient.

Where immobilisation is needed, the necessary rigidity is incorporated.

Only if individually designed, cut, made, and fitted for the one patient who is to wear it can a support be effective in the application of the necessary corrective and supportive forces on the body to aid reconstruction in the patient.

Total Liver Extract for Parenteral Injection

Hepolon is produced by improved processes which conserve all the known hæmatopoietic principles of the whole liver ; it gives no reactions for histamine or undesirable protein. Hepolon approximates to the extract described by Gänsslen ; later extracts have been described as of narrower therapeutic value.

Hepolon not only passes the highest clinical tests for potency against pernicious anæmia but contains Whipple's factor, Wills's factor, riboflavin, nicotinic acid, and the hæmatinic minerals of liver.

Ampones of 2 ccm. box of 6, 6¹/₂, box of 12, 11 c., and box of 24, 24¹/₂. Rubber-capped vial of 19 ccm., 5 -, and of 59 ccm., 19 c.

For sustained control of gastric hyperacidity

NOVASORB

(Hydrated Magnesium Trisilicate)

Novasorb provides for sustained control over gastric hyperacidity without producing an alkaline condition in the stomach. It thus presents a desirable improvement over the older antacids, where control is limited to the immediate reaction and where continued administration of excess alkali may induce alkalosis.

High adsorptive properties

Will not give rise to alkalosis

With suitable doses, does not destroy peptic activity

A safe antacid for general use

The Novasorb brand of hydrated magnesium trisilicate was developed and introduced by Evans Fine Chemical Works and is based on original observations and clinical trials (Brit. med. J. 1936, I, 143, 205 and 254).

Issued in Powder and Tablet form.

DIPHENAN B.D.H.

A Non-toxic, Non-staining Oxyuricide

Children with threadworm infestation are often subject gastro-intestinal disturbances; thus, in the treatment this condition, it is important to choose a medicament which is not likely to cause any further upset.

Diphenan B.D.H. is not nauseating, it is colourless and practically tasteless and its action on the parasite established; Diphenan B.D.H. is, therefore, the most general useful anthelmintic for use in threadworm infestation in infants as well as in children and adults. Further information will be supplied on request.

THE BRITISH DRUG HOUSES LTD. LONDON N

Dist. Ed.

are you not prepared to enter into service under the new ?"

Each a question is premature. Before we answer this question need to know a lot more facts which are as yet not forthcoming. We need to be informed much more fully of all the "pros" and "cons." So far all we have heard about are the "cons"—direction, the prohibition of buying and selling our practices, no appeal other than to the Minister, civil servant status, etc., etc. We have all had a bellyful of these particularly indigestible "cons" and have had plenty of time to absorb them into our systems.

But what of the potential "pros," which when revealed may be a little more palatable? These "pros," which we should know and must know before we can reply to any referendum, are: (1) What is the proposed salary? (2) What are the hours of work to be? (3) What is the pension to be (if any)? (4) If the new service is to be pensionable, what adjustment will be made for the middle-aged practitioner who has only a limited period of pensionable service before him but has many years of undervalued N.H.I. service behind him? Until we know the answers to these questions (most especially (1), (2), and (3)), how on earth can we be expected to make any decision in replying to the referendum?

We need to know what our future income will be *vis à vis* our present income. We have school fees to pay, insurances, etc., etc., which for our personal future budgets demand this knowledge.

As for the working hours under the new Bill—we are told that the new N.H.S. will require about three times as many doctors as there are in practice to-day. It will obviously take many years to build up this extra strength of doctors. Presumably, then, when the scheme comes into force in 1948 the hours of work will be increased rather than decreased, and I doubt the paper-work will be stepped up tenfold. All this, of course, is far beyond a joke as the average G.P.'s home during the winter months is merely a place where he snatches a few meals and sleeps at night. In all conscience it is difficult enough for us now to do full justice to each of our patients during the winter. If we get more work (plus paper-work) piled upon us then the examination and careful treatment of patients during the winter months will become a pathetic caricature. And while all this welter of work is being prepared for, many of the country's workers are striking for a 40-hour week.

Mr. Bevan presumes to dictate to us—to direct us, to deny us the right of appeal to any soul other than himself. He intends to extract from us a forced loan to the Government in the shape of our practice capital on which he will graciously give us 24% (less tax) until we are 65 years old or die from overwork. Mr. Bevan proposes to do all this to us, but yet as not breathed a single word on the question of salary, hours of work, or pension. And all we do is to tiddle around and talk of a referendum on further negotiations.

The Bill will become law. How could it be otherwise when the continued four-figure existence of that huge majority in the House depends largely on their ability as "yes-men"? The Bill will go inexorably through the Parliamentary sausage machine, and will plop out of the far end all neatly tied up at both ends; and we, unless we wake up and get some unity among ourselves, will be neatly tied up in the middle of it.

Sir, it is high time we doctors forgot some of our bedside dignity and got angry, *really* angry, with this man who in the spare time he has left over from his housing problems presumes to dictate our lives to us. Let us tell him quite bluntly that we don't like his Bill; that we will not be directed; that we will not have our practice goodwill confiscated from us; that we will not accept what must entail longer hours of work; that we demand a channel of appeal other than to the Minister. In brief, let us tell him that we will neither operate nor co-operate in his scheme as it stands to-day. If Mr. Bevan then wishes to produce an alternative scheme let him consult with and be advised by the technicians who will have to operate it.

Above all, let us have unity among ourselves. Let us not fall victim to the dictator's policy of "divide and conquer." On the principles of direction and appeal alone our very liberty is seriously threatened. If there is any spirit left in the profession there can only be one reply to Mr. Bevan—a defiant, unequivocal "No!"—I am, etc.,

SIR,—The principles for which the medical profession (or some of it) is fighting have been clearly and repeatedly stated in this *Journal*. But the majority of the profession is, as Dr. R. S. V. Marshall (Aug. 10, p. 207) remarked, "apathetic, resigned, or ignorant," as are the people of this country at present—a state of affairs which is most striking to anyone like myself just returned from service overseas.

The Minister of Health cannot but succeed in his nationalization scheme under such circumstances, for the Bill merely has to become a law to disperse feeble opposition. Theoretically, of course, our resistance is bound to succeed. It is only a matter of numbers—in spite of the influence of the formidable "enemy within the gate."

Speaking for myself I shall leave this country permanently, like many others, if we fail and our work is controlled by a higher authority who is also a layman. I suppose that the Government intends to produce the required 15,000 doctors by means of one of its celebrated statistical sleights of hand; and as there are no more gullible people than the British everything will be all right—except for the patient.—I am, etc.,

Airborne Forces Club.

C. J. R. JACOB.

SIR,—You must be deploring the amount of letter space you would normally devote to technical correspondence but must now perforce allow to be encroached on by "medico-politics," a new subject and one impressed upon the profession's attention from without. Yet you have not wasted this space if, as certainly appears, you have clarified some of the muddled thinking which seems inseparable from this new specialty.

On the part of His Majesty's Ministers one cannot diagnose muddled thinking until long-headed scheming is eliminated: apparent amblyopia may be deliberate shutting of the eyes. But there remains plenty of genuine naïveté, never better exemplified than by Mr. Bevan's delicious recent plaint to the general effect that his Government can easily foist upon the public health schemes which nobody wants, but that only nurses and doctors can translate them into reality.

From schoolboy days I seem to remember the pathetic bleatings of dominies who protested *ad nauseam* that they could provide every facility for learning, yet the "educand" would in the nature of things learn nothing but by his own efforts. (I then cherished, being at the "age without pity," unworthy suspicions that there might be such a person as a bad teacher here and there, and that this might be a bad doctrine conveniently propagated in order to make his detection difficult. But now that an increasingly powerful group in our own profession so often echoes the pedagogue's refrain by way of explaining why the patient is no better—I refer of course to the learned faculty of psychiatrists—such puerile doubts must clearly be dismissed.)

The teacher is right in his contention, for he offers the crystal fountain of knowledge, and if his alumni will not drink they have themselves to blame for the very obvious social and economic advantages which will pass by. But I cannot for the life of me see how the argument applies the other way round to the turbid waters of Socialism, which, as Prof. K. Douglas Wilkinson (Aug. 24, p. 272) so ably points out, have a bitter taste to the more energetic and useful doctor, and the imbibing of which can only occasion social and economic disadvantages to such a man. The Socialists say: "We have a plan to make your work monotonous and to reduce your income, but our plan will fail without your loyal co-operation."

The profession itself seems almost equally muddle-headed, as to the organization of its counter-measures. It takes two to make a negotiation no less than a quarrel, and the wisdom of the proposed referendum is open to doubt in view of the fact that the only sign of ministerial consistency has been a declared and inflexible refusal to do any negotiating. And another abortive referendum is unthinkable at a time when the profession has such need to conserve its funds.

I submit with humble deference that the only relevant question to print and post is: "What are you doing or going to do about the projected scheme?" Some men and women are already up and doing, for I know those who are leaving these shores or preparing to go: they are brave and adventurous people. I know others who are studying hard for higher diplomas, and they are still braver and more venturesome, since

Government service (e.g., the Colonial Medical Service) so often discounts and discredits the better-qualified when promotion is in issue. Such a question allows scope, and if the replies can be deciphered they must make interesting reading to the public, the Government, and the medical profession itself. Find as a fact that 79.81% of those who have any views on the matter are prepared to negotiate with a non-negotiator, and the moral, if any, is hard to see. It could be an index of Christian toleration, but some of us are Jews and Buddhists. But find as a fact that 79.81% are anxious to become Civil Servants, or willing to drift anywhere with the political wind, and the moral is plain: let them have it good and proper, and henceforth devote your valuable pages to facts and figures.—I am, etc.,

Stratford-on-Avon.

PETER PARRY.

SIR,—It is indeed a shocking thing, as Prof. K. Douglas Wilkinson points out (Aug. 24, p. 272), that the doctor in future is hardly likely to "work longer than 48 hours a week," and that "the practitioner who in the past has made £800 or £900 a year is to get more, but the able, hard-working, more highly qualified, more successful doctor who may have made as much as £3,500 is to get less . . ." It is simply dreadful to feel "that doctors will be less efficient, will not be proud of their profession, will tend to resemble their peacetime counterpart in the Services, do as little medical work as possible, and that poorly," merely because they will not have the opportunity to make £3,500 a year or more. Again, the "poor stick" of the future working in a sort of "telephone service" will probably have had a "free education" and "speak B.B.C. English." Could degradation indeed go further?

At the same time, I am afraid I cannot quite follow Prof. Wilkinson's reasoning. He writes: "As a learned profession medicine is dead." Of course it is, but it was no "pink giant" that killed it nor even a pink elephant, but Pasteur when he assisted at the birth of medicine as a science and thereby declared war on the childish assumption that medicine can be learned from books, and put an end to quotations from the ancients as a substitute for knowledge—unless as a preamble to one of the annual addresses, by way of a pretence to scholarship.

But quite frankly I do not feel from a perusal of his letter that that is what your correspondent really means, although that is what he says. I think what he really means is that in future medicine will be no place for a snob, still less for a money-maker. Indeed, to quote the words of the editor of an ancient but vigorous contemporary, "the scope for bedside manner and humbug is steadily diminishing."—I am, etc.,

London, W 6.

LAURA L. BATEMAN.

SIR,—I should like to congratulate Prof. K. D. Wilkinson on his very excellent letter (Aug. 24, p. 272). It is quite the best and most straightforward one we have had. If only the B.M.A. members would stick together they could call the tune, but they I not—already there are blacklegs looking out for the best for themselves under the new Service.

o doctor ever talked of "striking." He could always see patients, but just sign no forms at all—National Health, death certificates, etc.—and there would be chaos. Everyone else can strike, but doctors doing so would just be "not done" says the Government Press.—I am, etc.,

Leamington Spa

D. F. L. CROFT.

Reassuring the Profession

SIR,—One feels that only a sense of economic insecurity will prevent a 100% vote against the National Health Service Bill in its present form. Most men under 50 have so many commitments that they cannot lightly contemplate remaining out of a scheme which seems to promise financial security and compensation. They feel even against their better judgment that they cannot afford to stay out. Reassure these that the profession, discarding all contracts (including the present National Health Insurance agreements), is prepared to run the health services of the country on a fee-paying basis so that no one may starve, and you will have the bulk of the profession with you. But reassurement they must have.

As for the younger members of the profession (and particularly those back from the Forces), they must be disillusion about the terms of the present Bill. Show them that it is "pig in a poke," that it guarantees terms of service in neither time nor income, perpetuates all the disadvantages of present day practice without any compensating advantages, that it means harder work, longer hours, and a smaller income, at a time when wages all round are going up—and for what?—the promise of a pension which in 10, 15, or 20 years will bear no relationship to the cost of living.

Unless these facts are more widely known there is a very grave fear that the voting may in spite of us go against the Association's policy—and simply because few men know the facts of the situation. A leader on these lines would, one feels, do more to clarify the position than a dozen verbatim accounts of Representative Meetings.—I am, etc.,

London, N.6.

W. LEES TEMPLETON.

Principles and Policies

SIR,—A careful study of the proceedings of the Representative Body at its last meeting makes it clear that the issue lies between the policy of the B.M.A. and that of the Government. Why then all the talk about "principles" which characterized so many of the speeches? Presumably the reference was to the Seven Principles enunciated by the Council for discussion by the R.B. at the meeting in May, but consideration of these in the light of the definitions of the word "principle" in the Oxford English Dictionary shows that most of them are matters of policy and in no way true principles. It is important that the distinction should be clearly recognized. Many will fight to the death for a principle; few would carry opposition to a policy so far. The O.E.D. definitions most applicable appear to be: (1) "A tenet forming the ground of, or held to be essential to, a system of thought or belief"; (2) "a fundamental motive or reason of action, especially one consciously recognized and followed."

"The medical profession should remain free to exercise the art and science of medicine according to its traditions, standards, and knowledge, the individual doctor retaining full responsibility for the care of the patient, freedom of judgment, action, speech, and publication, without interference in his professional work" clearly conforms to the definitions, but it seems to me that the rest of the so-called principles are either comprehended in it or are matters of opinion or policy.

I cannot find sufficient reason for refusal to co-operate with the Minister on the ground of principle. Dr. Dain says that the basic salary means a "partial transference of the doctor's responsibility from the patient to the person who pays the bill." This may be so, but in "the good old days" it was customary for wealthy people to pay for the medical attendance of their servants. Did the profession protest against this custom on the ground of principle? On the contrary, the fact that the N.H.I.A. would have practically abolished it was one reason for the opposition of a large section of the profession to Mr. Lloyd George's Bill. The practitioner will find it easier to protect the interests of his patient when a department is the "person who pays the bill" than when the latter was the squire who wanted his gamekeeper ready for a big shoot or his butler fit for a house party.

In the matter of "direction," has a practitioner ever been absolutely free to practise where he pleased? If there was no vacancy in the place of his choice, or if he had not sufficient capital to purchase a practice or partnership, it is true that he was free to "squat"—but at the price of ostracism by his fellows. Are there really many other workers who are not subject to direction in one form or another? Is there any essential difference between the compulsory acquisition by the State of the goodwill of medical practices and the compulsory acquisition of the Bank of England and the mining industry?

The policy of the present Government is Socialist. We as a profession are essentially individualists, but it does not appear to me to be consonant with our dignity to refuse to work a National Health Service based on a policy for which the majority of our patients voted at the general election. I am not a Socialist. I have voted for the Conservative candidate in my Division at every election during the last 42 years, so that I have

tical bias in favour of this N.H.S. Bill, which frankly I st. It deprives me of certain cherished privileges, affronts dignity, and interferes with me, as I think, unnecessarily. I nt to be free to practise in my own way, in my own place ; when I retire, to hand over my patients to a man of my n choice. I am sure that most of my colleagues share these timents, but let us be honest, keep our sense of proportion, I not talk about "principle" when we really mean "policy." Two world wars during one generation have shaken the ndations of our civilization, and we live in a period of olution, bloodless as yet, but none the less real. It seems me lamentable that the Minister of Health should be able say—with some justification—that "the spokesmen of some ments of the medical profession have become the most ctionary politicians in Great Britain." One would have ex- ted a learned and humane profession to take the lead in aptation to the changed conditions of life. To refuse to empt to work an Act of Parliament appears to me to be democratic and indefensible. To insist on Regulations em- dying safeguards to our remaining liberties, adequate remun- tion, and equitable terms of service as an essential condition taking service under the Act is a right which we share with other workers, and I hope that our negotiators will be in- ducted to take this course. For myself, being a law-abiding izen, when this Bill becomes law I shall feel obliged to work o the best of my ability—and I am very sure that I shall not merely a member of a small minority.—I am, etc.,

luckfastleigh.

SYDNEY R. WILLIAMS.

Resistance

SIR,—Britain is emerging from a situation in which she im- rilled her existence in the name of democracy to protect lated minorities in Europe against the domination of a group norarily in a position to infringe their rights and impose olitical doctrines upon them—a group arrogantly acclaiming emselves to be in the vanguard of progress. Owing to the despread cultivation of arrogance and the infliction of cruelty, r political ends these cults became conventional in Germany, und expression during the war, and created the animosity wards the race which still prevails. These acquired character- ics were responsible for the war and the manner in which it as conducted ; but the issue which determined Britain's atti- de was whether a powerful group, or combination of groups, ould arrogate the rights of various weaker groups, dispose their properties, and impose political doctrines upon them. ough there was no semblance in the ethical principles vio- ted, the Labour programme regarding the medical profession nd other minorities was designed, directly or indirectly, to ach a similar objective.

It is true that in a democratic sense the medical profession, ke other minorities, is represented in the Government ; but the ctual position is that it is governed by the representatives of bour. It is also, and more truly, represented by distinguished edical men with high qualifications and positions won in open ompetition. These distinguished men have made the problems f health a life study, and have consistently advocated reforms i the health services. Many of them have had these services nder constant observation throughout long careers and have tilized their exceptional advantages to consider the advisability f the various changes which have been periodically advocated. hey necessarily provide the most reliable information avail- able, including that on which the contemplated changes are ased ; yet recommendations, which they regard as of primary mportance, are being set aside by men of whom few can claim o have made a contribution of value to this or any other bject.

If it could be claimed that the tribunal was impartial the visdom of resistance would be questionable ; but it is notorious hat the essential qualification for membership is exceptional roficiency in fostering and appealing to prejudice.—I am, etc.,

Amersham.

H. MACNAUGHTON-JONES.

H. G. Wells

SIR,—May I express my appreciation of your very brilliant eader on the subject of Mr. Wells (Aug. 24, p. 268) ? I feel hat I should like to call attention to a volume not quoted in your article—viz., the *Textbook of Zoology*. This, said by

some to be one of his first books, and now under dual author- ship with A. M. Davis, I found very valuable during my first ear as a medical student. The book is a literary classic and a joy to read. It is enriched by many concise diagrams and there is a very useful appendix of practical suggestions at the end of the work. Another very precise and fascinating small volume is his *Short History of the World*, published by Watts, probably a condensation of his monumental *Outline*, cited in your leader. I observed a new edition of the *Short History* has recently been published taking readers to the victorious conclusion of the war against the tripartite powers.

While he was often very provocative in his utterance, I feel no one can afford lightly to dismiss the writings of such a profound thinker and scientist. He was one who knew how to arrest the popular imagination and I have always felt that his film *The Shape of Things to Come* is one of the most searching pieces of anti-war propaganda ever conceived. That film is a plain warning for all mankind and still has its message for our atomic age. I feel no one had a clearer conception of the full implications of modern science and of its use and misuse by man.—I am, etc.,

Dunfermline, Fife.

J. B. GURNEY SMITH.

On Reverence for Authority

SIR,—In the *Journal* of Aug. 24 you publish an appreciation of H. G. Wells in a leading article. In it you state, as if it were a thing to be admired, that he hated cant, pomp, and reverence for authority. We all hate cant because it is a vice. With his hatred of pomp many may disagree. It can be very pleasant and enjoyable, and it is the enemy of drabness. It appeals to some desire in the ordinary man, and at some time or other we all indulge in it, both in our public and private lives. It is not essentially wrong, and so it may not be hated. The vast majority will, I think, agree that reverence for authority is not a thing to be hated, but on the contrary that it is a virtue to be practised and admired, and will hold in suspicion the man who teaches otherwise. Authority is necessary in every society and every civilization, and if it is to work its greatest good it needs the reverence of those subject to it. Without this it becomes a tyranny.

The profession of medicine is an excellent example of the necessity of reverence for authority. Through it it lives and has its being. Upon it rests the doctor-patient relationship. Take it away, and the patient has recourse to the thousand cures of his well-meaning friends, who back their advice with the authority of friends.

From the general practitioner take his reverence for the opinion of his better-qualified or more experienced colleagues, and what will become of him in times of difficulty and of crisis? Without it what value is there in higher degrees and postgraduate courses? Our specialists dare not attempt their delicate, difficult, and dangerous tasks if they had no trust in the authorities they have studied. Why then should professors write their textbooks or research workers publish their findings? Why should we have medical journals, and why should they publish papers by the leaders of our profession, or have such features as "Any Questions"? Is it not because we have reverence for authority, and because we recognize that it is essential in the practice of medicine?

We look to leading articles for authoritative statements upon matters of moment and are guided by them. Yet with the authority of the editorial chair we are asked to admire in a man the fact that he hated reverence for authority.—I am, etc.,

Clones.

W. G. KIERANS.

* * We stated what we believed to be the outstanding characteristics of a remarkable man. The word "pomp" was used in the sense of the dictionary definitions: "ostentatious display ; parade ; vainglory" ; in the Prayer Book sense of "the pomps and vanities of the wicked world." It would not be difficult to sustain the thesis that "reverence for authority" has often impeded the advance of medicine. Reverence for the authority of Galen made him the dictator of medical thought for a thousand years—in spite of Galen's warning "that those who are enslaved to their sects are not merely devoid of all sound knowledge, but they will not even stop to learn."—ED., *B.M.J.*

Book Reviewing

SIR,—Most of your correspondents on this subject have pressed for signed reviews; I should like also to give my vote in favour of signed reviews, but not necessarily against unsigned ones. There is another side to the question which those who have not experienced editorial responsibility may not appreciate.

What is the object of a review? Surely it is neither to encourage nor to discourage the author, neither to flatter nor to castigate him, but rather to serve as a guide to the prospective reader. The latter wants information on three main points; he wants to know: (1) What is the scope of the book? And is the subject well covered? (2) Is the information conveyed satisfactory: that is, does it either conform to the generally accepted views of the day or represent the opinions of one recognized school of thought; or, if it presents the author's individual opinions, are these reasonable hypotheses well supported by reliable data or by adequate personal experience? (3) Is the subject-matter well presented? Additional information, on the aesthetic effect of the book for example, may not be out of place but is really of secondary importance.

It is not always easy for an editor to choose a reviewer whom he can trust to give a fair and balanced opinion on all these three points. The acknowledged authority on his subject may have views which happen to be directly opposed to those of the author, so that, unless of course the book achieves the miracle of conversion, his answer to question (2) may be perfunctory if he can sink his own individuality, or prejudiced if he cannot. On question (3) the expert knows his subject so well that he does not always appreciate the point of view of the student (*sensu lato*) as fully as might a reviewer less familiar with the subject.

You, Sir, no doubt have a very wide choice of willing reviewers from whom you can always select exactly the right man for each book, but editors are not always so fortunately placed; and in some parts of the Empire experts are rare and usually far too busy to write reviews. The editor's choice may then lie between an expert on the subject, on whom he cannot count to give an unbiased review (or in fact any review at all), and a tried and trusted but less specialized reviewer—to whom in any case he may have to send the book a year later when he has at last recovered it from the defaulting expert. In such circumstances it may not be politic, nor is it always fair on the reviewer, to ask him to sign his review, and the reader must trust the editor. There are other circumstances in which reviews should remain anonymous, but I do not agree with "One of Your Reviewers" that complete objectivity cannot be obtained without anonymity. However, the editor must take a great measure of responsibility if he publishes unsigned reviews, and I consider that all contentious or highly critical reviews should be signed. Mr. H. Osmond Clarke (July 20, p. 102) seems to suggest that the feelings of the author should be given first consideration and that highly critical reviews should not be published at all. Such censoring would in my opinion be unfair to your readers.

We have had the opinion of "One of Your Reviewers"; it would be interesting to know the results of a questionnaire sent to your reviewers. It is my guess that a majority would be in favour of anonymity but that the reasons they would give in support of their vote would be unconvincing; however, I believe that the real reason that they may favour anonymity is much more laudable than the one Mr. Osmond Clarke suggests.

Following along Mr. Hamilton Bailey's diversion (Aug. 3, p. 173), I can give him one reason why more space is given to foreign books: it is because there are more foreign books. In the United States alone there are probably two or three times as many medical books published as in the British Commonwealth. Further, American publishers are far more enterprising in sending out their books for review. Even if allowances are made for what I believe to be a fact, namely that proportionately more American books are unworthy of a review, at least in this country, I cannot help feeling that Dr. E. A. McWhirter's statistics (p. 173) on pride of place in your review columns—26 for American and 22 for British—suggest a pro-British bias, rather than the prejudice in favour of American books of which he and Mr. Hamilton Bailey appear to accuse you: I feel sure that you entertain no such prejudices and that you are guided

solely by your reviewers' opinions. The latter correspondent's suggestion that you should adopt a weighted quota system in your choice of the reviews you publish is in my opinion monstrous, and most insulting to British authors and publishers. Our medical books (and above all those written by Mr. Hamilton Bailey) need no special boosting and can surely hold their own with those from any foreign country; if they cannot then it is time we did something about it other than asking editors for preferential treatment.—I am, etc.,

London, W.1.

L. EVERARD NAPIER.

The London College of Osteopathy

SIR,—Dr. George Macdonald's statement (Aug. 31, p. 312) that "whatever the orthopaedic surgeons or the physiotherapists know of manipulation has been gleaned from the osteopaths" is absolutely untrue. We have learnt nothing about manipulation from osteopaths. The present position of manipulative surgery as an integral part of orthopaedic surgery is entirely due to Herbert Barker, who is not an osteopath and has never practised osteopathy.

Bone-setting is an essentially British product which flourished in this country for 200 years before A. T. Still was born. Admittedly it was looked down upon and neglected by the medical profession until Barker compelled attention to the good that there might be in it. The osteopaths were quick to take advantage of this and they have tried ever since to ride home on the backs of the bone-setters. But osteopathy has nothing whatever to do with bone-setting or manipulative surgery properly so called. It is a typical American stunt and its claims have been investigated up to the hilt and found wanting.

It is true that many osteopaths practise bone-setting or manipulative surgery and call it osteopathy. Obviously the manipulation of a stiff foot, a knee, a shoulder, or a sacroiliac joint, if properly done, may be as successful in the hands of an osteopath as in those of a bone-setter or an orthopaedic surgeon, but it is not osteopathy. Even the manipulation of a back for chronic backstrain is not osteopathy, but straightforward manipulative surgery. The essence of osteopathy is the treatment of remote conditions by the "adjustment" of the osteopathic "lesion."

Dr. Macdonald's admission that he does not know what the osteopathic "lesion" is is almost illuminating. I always thought that osteopaths claimed to know exactly what was the matter. His latest attempt to identify it with the prolapsed intervertebral disk is delightfully ingenuous, for if this could be established it would be the end of osteopathy. Who wants to manipulate a prolapsed disk anyway?

A registered medical practitioner in this country is free to practise any form of therapy he pleases. But medical men are by no means immune to credulity and it is right that they should be told what they are in for before they fall for the advertisement of the London College of Osteopathy. The Select Committee of the House of Lords "rightly exposed" very much more than "the inadequately trained osteopath" it exposed osteopathy.—I am, etc.,

London, W.1.

A. S. BLUNDELL BANKART.

SIR,—In reply to Sir Morton Smart's letter (Aug. 17, p. 245), a postgraduate course in osteopathy has been organized by the British Osteopathic Association. The course is open to qualified medical men only, takes nine months, starts on October 1, and will be held at the British Osteopathic Association Clinic in Dorset Square.

As to the standing of the college, the lecturers are clinical teachers who have all been trained in America, and some of them are on the British Medical Register. Both the clinic, which was founded in 1938, and the college are supported by voluntary contributions, and the staff is almost entirely honorary.

The British School of Osteopathy on the other hand teaches students *ab initio*, and is in no way associated with this postgraduate college.

The British Osteopathic Association feel that by adopting this policy all that is best in osteopathy, as taught and practised in America, will be made available to qualified medical men in this country.—I am, etc.,

London, N.W.1.

W. HARGRAVE-WILSON.

Amenorrhoea during Internment

SIR,—I have read with great interest the experiences of Dr. Annie Sydenham (Aug. 3, p. 159) and Dr. W. P. Grieve (Aug. 17, p. 243) on amenorrhoea during internment, and I should like to record some criticisms and observations of my own. On careful analysis of Dr. Sydenham's paper I am unable to find sufficient support for her contention that a nutritional deficiency, particularly of the first-class proteins, was responsible for the amenorrhoea. Two of her own statements entirely destroy this hypothesis. First, Dr. Sydenham says that "... in most instances amenorrhoea dated from December, 1941, before the effects of undernourishment on general metabolism could have been manifest." And then she concludes her article with the observation that "... poorer Chinese patients who came to gynaecological clinics before the war were not suffering from amenorrhoea, although they were living on a diet similar to ours. . . ."

In a previous communication (March 9, p. 347) I reported on 39 cases of menstrual delay in the W.A.A.F., and I found that in spite of an adequate protein diet of over 100 g. per day, 46% of all recruits could expect amenorrhoea for a varying period up to six months after entry into the Service. In every case the menstrual period immediately succeeding entry was absent. That mere entry into the W.A.A.F. was probably the operative factor was illustrated by a number of girls who stopped bleeding on the day they donned uniform, when the menstrual period had lasted only one or two days, and whose normal menstrual bleeding time was five to six days. Menstruation usually returned after a delay of six to seven months, although no radical improvement in their diet had occurred during that time. It appears therefore that the exciting factor was the sudden change of environment.

However, to state that the symptom-complex is due to "change of environment" or "emotional shock" is not enough. We must attempt to explain why psychic trauma resulting from environmental stress can inhibit one of the most fundamental biological processes in the human female. What link in the endocrine chain which leads to menstrual bleeding is broken? As Dr. Grieve says, this is a matter of conjecture.

But I should like to advance a hypothesis which is in accord with the clinical and experimental data at our disposal. The hypothalamus is recognized as the centre for autonomic control, and in response to an environmental stimulus will bring about the release of adrenaline and acetylcholine. It has been shown by Taubenhaus, M., and Soskin, Samuel (*Endocrinology*, 1941, 29, 958) that acetylcholine placed directly on the pituitary gland leads to the production of luteal hormone and hyperaemia of the uterus, while adrenaline inhibits the luteal hormone. In response to environmental stress some women will secrete an excess of adrenaline, thus preventing menstrual bleeding, due to either (1) a deficiency of luteal hormone and consequently corpora lutea, or (2) insufficient vascular dilatation of the endometrium.

Our knowledge of the control of the menstrual cycle, and in particular of the bleeding phase, is as yet incomplete. It is to be hoped however that others like Drs. Sydenham and Grieve will come forward with their experiences so that the various pieces of this puzzling phenomenon may be accurately fitted together.—I am, etc.,

Bray, Eire.

N. SHER.

Clinical Pathology and General Practice

SIR,—Dr. G. A. Harrison (Aug. 24, p. 278) suggests that family doctors should be trained to do simple laboratory tests. I believe G.P.s should undertake such tests, first, as aids to diagnosis, and secondly, to maintain interest in medicine when overwork tends to diminish it. Clinical judgment is fallible, and the G.P. puts his trust in laboratory test results. Pathologists say laboratory tests are fallible and trust should be put in clinical judgment.

I suggest that the Association of Clinical Pathologists should select and standardize certain simple laboratory tests for G.P.s with detailed instructions, so that the practitioners' results may be trustworthy, comparable, and worth knowing. For example, how to make a blood film should include how to clean and keep clean glass slides. Obermayer's reaction is simple to do,

but is it worth doing? It is easier to be confident of the results of an Esbach test than of the interpretation of a blood film. Until recently I used to estimate the sedimentation rate by Westergren's method and took comfort if in some obscure case the result was within normal limits. I took the first hour's reading only, as I was usually out on visits after that. A pathologist informed me that a single sedimentation rate was without significance, that he ignored the first hour's reading, that the test was more for prognosis than diagnosis, and that there were better methods than Westergren's.

Dispensers can be taught to do some simple tests—e.g., albumin, sugar, acetone in urine. One retail pharmacist told me he could not care less about anything than clinical pathology. Dr. Harrison mentions the difficulties of securing help from trained laboratory technicians. So we shall have to do the work ourselves. But who is to train us, Dr. Harrison?—I am, etc.,

Stoke-on-Trent.

P. H. KENDALL.

A Case of Presumed Hypoglycaemia

SIR,—A man aged 30, having apparently cycled from London to Hove (over 50 miles), was found collapsed beside his damaged bicycle. He was brought into hospital in a disorientated and hilarious condition, and soon became comatose. Before becoming completely unconscious, in reply to questioning, he denied having diabetes. When seen he was pale and had evidently recently sweated profusely. His pupils were wide and his eyes roving. He could not be roused. There was no smell of alcohol in his breath, nor evidence of poison in his mouth. Examination revealed no physical injury. He had not bitten his tongue nor been incontinent. His muscle tone and reflexes were normal. His respiration was normal, and he was not cyanosed. His heart was normal, and pulse strong and regular at 80 beats per minute. His blood pressure was 125/80. A specimen of urine obtained by catheter contained neither albumin nor sugar.

It was thought that he might be suffering from hypoglycaemia, narcotic poisoning, or post-epileptic coma. Facilities for obtaining a blood sugar estimation not being immediately available, and the giving of glucose being a harmless and simple procedure, it was decided to do that before considering whether to wash out the stomach in search of a hypothetical narcotic poison. Accordingly 30 ml. of a 50% solution of glucose was injected intravenously. Five minutes later the patient was in full possession of all his faculties.

The patient stated that he had often cycled from London to Hove, but that on previous occasions he had eaten a packet of raisins on the journey. He could recollect trying to dismount from his cycle, overbalancing, and damaging it.—I am, etc.,

*Brighton.

R. S. SAXTON.

Postgraduate Study for American Doctors

SIR,—The question of providing facilities for postgraduate study in this country for American, Colonial, and foreign practitioners is of importance not only from a medical but also from a national standpoint. London has always attracted a number of Canadian, South African, and Australian postgraduates who have come to this country in order to obtain a higher qualification, such as the M.R.C.P., F.R.C.S., or one of the special diplomas; and these students have been catered for in the same way as British postgraduates.

Before the war a considerable number of American and Colonial practitioners used to attend postgraduate courses in Vienna. These courses were very popular—not only affording members an opportunity of advancing their knowledge, but also giving them an interesting European holiday. At the end of a short course of one to three months' study at one of the hospitals of the Vienna Poly Clinic a certificate was awarded which gradually came to be regarded as a tangible mark of professional achievement.

It will obviously be some years before Vienna is rehabilitated. I have had an opportunity of obtaining the opinions of a number of American doctors on the question of postgraduate study in London, and I have received enthusiastic support from

a large number. There are many reasons why we should welcome American doctors to this country, and if the value of the postgraduate teaching in the London hospitals were suitably brought to their notice, coupled with the attraction of a certificate after a short period of study, I have no doubt London could become the new Mecca for American doctors desiring postgraduate study. There is abundance of clinical material in London, and many of our teachers would be only too pleased to welcome American doctors to their clinics. I think the time is now very opportune for furthering this project. There are various postgraduate organizations in this country, and I would welcome correspondence from those interested.—I am, etc.,

London, W.1.

J. LANDMAN.

Colonial Medical Service

SIR,—I should like to congratulate "Another West Coast" (June 15, p. 931) on his lucid exposition of the conditions in the Colonial Medical Service. His words are, I consider, equally applicable to conditions on the East Coast, and they might with advantage be substituted for the official misrepresentations that appear as advertisements for the service.

There is undoubtedly a certain fascination in working under primitive conditions. In earlier years professional rustiness, from working under these conditions, was remedied by study leave; while a reasonable margin between salary and expenses enabled a decent vacation leave to freshen the intellect. Now unfortunately a rise in cost of living, officially admitted as over 66%, and a very considerable increase in taxation both direct and indirect, have wiped out any margin, leaving a mere existence without the advantages in return that may be obtained in Europe. It is, I think, a pity that short service commissions on any lines could not be instituted. These would enable men to see for themselves the advantages and disadvantages and to leave without financial sacrifice if they considered the latter to predominate.—I am, etc.,

"EAST COAST M.O."

SIR,—The conditions described by "Another West Coast" in his letter apply equally well here in Northern Rhodesia. I would add to the maxims for the worldly-wise that the medical officer should tread delicately in his dealings with missionary societies; and he should not stress unduly the need for improvement in the conditions of his hospitals, as this means expenditure of money—a commodity of which most Colonies are short.—I am, etc.,

"NORTHERN RHODESIA."

State Medical Service and Free Speech

SIR,—Many questions have been raised in connexion with service in a State Medical Service. I am prompted to ask whether freedom of speech will be retained intact; or whether permission to express an opinion or criticism will be obligatory, as it is, for instance, in certain other medical services? I cannot help feeling that a hint of constraint may creep in if published letters have to bear some such addition as: "Approved by the Deputy Under-Commissar; Medical Division, Dept. 46A; Region 89; Ref. 6584/vft34/t9."

Possibly it is fortunate that salt mines are not a feature of the British countryside.—I am, etc.,

GLASGOW, C.3.

J. RONALD.

Entertaining Allowance, Royal Navy

SIR,—The recent Admiralty Fleet Orders (453-457) set out the entertaining allowance for Executive Officers, Royal Marine Officers, Wren Officers, Engineer Officers, Supply Officers (Paymaster Branch), but no mention is made of the Medical Branch. For many years the Medical Branch have felt that they have a very justified grievance in that senior officers have no entertaining allowance and yet are expected to give hospitality to Admiralty visitors and anyone whom Parliament wishes to be entertained at the hospital. During the war years this was a very heavy item and numerous foreign and allied officers were given hospitality on many occasions.

It seems that every branch of the Navy is given entertaining allowance except the Medical Branch and this surely should be put right.—I am, etc.,

London, W.1.

CECIL P. G. WAKELEY.

Obituary

A. TUDOR EDWARDS, M.D., M.Ch., F.R.C.S.

Arthur Tudor Edwards died suddenly at the age of 56 on Aug. 25 while on holiday at St. Enodoc, Cornwall. He had been in poor health for some weeks before this, but though the serious nature of his underlying illness was known to his friends and colleagues his death has come as a severe shock and a cruel blow.

He was the elder son of William Edwards, J.P., of Swansea and was educated at Mill Hill School and St. John's College, Cambridge. From there he went to the Middlesex Hospital and qualified in 1913. He served as surgical registrar and obtained his M.Chir. and F.R.C.S. in 1915 and then joined the R.A.M.C., in which he attained the rank of major. At the end of the 1914-18 war he was appointed assistant surgeon to the Westminster Hospital and surgeon to the Brompton Hospital for Diseases of the Chest. There now followed years of intense surgical activity which continued almost unchecked until the beginning of the recent war, and which rapidly earned him an international reputation at an early age.

[Howard Carter]

Although his reputation rests almost entirely on his pioneer work in thoracic surgery it should not be forgotten that Tudor Edwards was also an unusually able general surgeon, a fact that is not without significance in considering the excellence of his thoracic work and in regard to the present tendency for young surgeons to undertake a major speciality before they have attained general skill and experience. In addition to his years of general surgery at the Westminster Hospital he was for many years surgeon to Queen Mary's Hospital, Roehampton, where the difficult and complex problems of the war pensioners demanded the skill of a surgeon of his high calibre. While he was building his reputation as a thoracic surgeon he was at Queen Mary's doing excellent work on the abdomen, notably in connexion with the aftermath of the large numbers of cases of gastro-jejunostomy performed during the 1914-18 war. His experience in gastro-jejunal ulceration and gastro-colic fistula must have been second to none in this country.

The brilliance of his life-work lay, however, in thoracic surgery, and it may be said that he found it an almost untouched field and left it a sturdy, established, and flourishing speciality. It is indeed remarkable to consider that in 1921, when he first joined the staff of the Brompton, the surgery of the thorax scarcely existed in England, apart from an occasional immature thoracoplasty or operation for empyema. The experiences of the 1914-18 war had shown that the interior of the chest tolerated intervention better than had been thought, but the major problems of bronchial carcinoma, bronchiectasis, carcinoma of the oesophagus, intrathoracic cysts and tumours had been quite untouched. The surgery of pulmonary tuberculosis was slightly more advanced but was still in its infancy and had engendered but little confidence. It can truly be said that the name of Tudor Edwards will always be associated with the magnificent development of the surgery of these conditions, the success of which is now so well recognized as to need no emphasis. The way was undoubtedly hard and at times bitter, for in addition to the difficulties of technical achievement there were the difficulties of reaction and conservatism. It needed a surgeon of Tudor Edwards's brilliance and drive to overcome them, but soon he was finding a steady and increasing stream of thoracic surgical material referred to him which rapidly became a flood-tide. At the peak of his career as an operating surgeon he was doing an enormous amount of heavy surgery, and there can be little doubt that

the physical strain and attendant mental anxieties of this difficult work contributed to the development of the illness which eventually overtook him.

His ordinary afternoon operating sessions at the Brompton Hospital, which often went on until after 9 p.m., were always attended by a large crowd of visitors, sometimes including representatives from as many as a dozen different countries. As an operator he was superb, and as soon as he began a major thoracic case it was clear that he was a truly gifted surgeon. He was at his very best in those difficult intrathoracic problems that had in the past defeated so many surgeons. Besides being a skilled operator he was an experienced clinician—an attribute that contributed in no small part to his success. To work with Tudor Edwards was the ambition of most young thoracic surgeons, and many were the requests received from aspirants all over the world to act as his assistant. There are many established thoracic surgeons now who owe their training to what they learnt from him. There are very few thoracic surgeons indeed who have not benefited by his teaching and influence even if they have not actually served as his assistant.

In addition to a large consulting practice he held numerous other hospital appointments, notably consultant surgeon to King Edward VII Sanatorium, Midhurst, thoracic surgeon to the L.C.C., in which he was responsible for organizing thoracic surgical units, and to Queen Alexandra's Hospital, Millbank. In 1936 he was invited to take charge of a newly formed Department of Thoracic Surgery at the London Hospital, and in accepting this post resigned from his surgeoncy at the Westminster Hospital and devoted his whole time to chest surgery. The volume of work that he was doing is shown by his Harveian Lecture in 1939 on 199 cases of bronchiectasis treated by lobectomy and pneumonectomy. His writings on thoracic surgery were numerous and covered aspects of the whole field. His last important contribution was in the first number of the new journal *Thorax*, in which he summarized his experiences in over 1,000 cases of bronchial carcinoma, including 70 cases in which he had performed pneumonectomy or lobectomy. This was the first presidential address to the new Association for the Study of Diseases of the Chest, in the formation of which his activity and influence had played a notable part. It was largely due to his patient and wise counsel that *Thorax* made its appearance this year under the joint auspices of the Association for the Study of Diseases of the Chest and the British Medical Association.

A year or two before the recent war he had a severe illness, but appeared to make a good recovery, only to suffer a relapse in the autumn of 1939. In spite of this he threw himself unstintingly into the numerous duties and tasks which befell him as the acknowledged leader of thoracic surgery in Great Britain. He organized the whole of the centres for the reception of thoracic casualties throughout the country, a work that entailed much long, difficult, and harassing travelling under war-time conditions. He was civilian adviser in thoracic surgery to the War Office, and as civilian consultant to the Royal Air Force he organized a special centre at Midhurst, the success of which was ensured by his undertaking regular frequent visits there for operating himself. In addition to all this and his numerous commitments on committees of national importance he accepted nomination and was elected to the Council of the Royal College of Surgeons in 1943. Although he well knew that he should avoid extra strain he shirked nothing, and this enormous zeal for work must have contributed to his sad and early death.

His loss is a great one. To his friends and colleagues he is irreplaceable. His death sees the closing of a chapter in the development of thoracic surgery in which, largely by his efforts, Great Britain was pre-eminent throughout the world. The success of the new chapter will be in part due to his teaching, training, and example. He was a charming and courteous colleague, kindly though intolerant of incompetence and ultra-conservatism. He was of handsome appearance, dark, and clearly possessed of a striking personality. It is sad that he did not live to enjoy the years of honour, renown, and achievement that were still due to him. He was at one time president of the Society of Thoracic Surgeons, was an Honorary Fellow of the American Society of Thoracic Surgeons, and had received honorary degrees in addition to other marks of recognition

from several European universities and learned societies. His married life was a very happy one, and he is survived by his wife, Evelyn, daughter of Dr. T. Hoskin. Her sorrow at his loss is shared by all his friends and associates and the numerous patients throughout the country and in many parts of the world who have cause to be grateful for his successful treatment.

Sir GORDON GORDON-TAYLOR writes: I knew Tudor Edwards for 35 years from the time that he came from Cambridge to Middlesex Hospital. He was my dresser, my house-surgeon, and he has remained my friend.

Tudor had set out from boyhood days to become a surgeon. He approached the specialty which he has done so much to advance and which has made his name world-famous through the proper avenue of general surgery. He served an apprenticeship with Bland-Sutton before the last Armageddon, learned fracture surgery at Wimereux under the guidance of that mechanical wizard Maurice Sinclair, studied his fellow-men amid the duress of the trenches in that icy winter of 1916-17, and established his reputation as a most skilful and brilliant surgeon in No. 6 Casualty Hospital at Barlin in an Army which rejoiced in Cuthbert Wallace as its consulting surgeon, and in which he could compete in friendly rivalry with that band of enthusiastic, able young surgeons gathered together under Wallace's aegis, all destined to attain first rank in the years to come.

The cessation of hostilities released one whose high surgical destiny seemed assured. Westminster Hospital, Brompton, the Ministry of Pensions were not slow to embrace the opportunity which lack of vision elsewhere had placed on their doorstep, and later on the London Hospital honoured Tudor by inviting him within their own portals.

The limitless opportunities which Brompton and his other large hospitals afforded Tudor enabled him to attain a reputation which extended from Orient to Occident, and from Norwegian waters to the lands under the Southern Cross. The written word is often a meretricious avenue to international reputation: Tudor Edwards's fame has rested and will rest on his deeds rather than words, although 33 papers under his name are chronicled in the *Cumulative Index* and there were other contributions to works on war surgery and various memoranda for the assistance of those called on to deal with injuries of the chest.

Tudor's chest-surgery was learned from no pioneer, but carved out of the hard rock of experience. He would have been the first to acknowledge the help, the vision, and the confidence of the physicians at Brompton who gave him opportunity, and in the early days particularly that of Dr. R. A. Young; his work was facilitated by the advances of anaesthesia, and his debt to Ivan Magill especially was always freely acknowledged; but his own brilliance, wisdom, experience, and courage made him the greatest thoracic surgeon of the world of his day.

Those who are reckoned great in surgery must among other obvious qualities have inspired their pupils and provided for their own succession. The torch of thoracic surgery which burned so brightly in his hand is already blazing in the grasp of his juniors, and the future of thoracic surgery is full of golden promise. Some may remember those lines from Homer's *Odyssey*: "For nothing is greater or better than this, when man and wife dwell in the house in harmony, a joy to their friends, but they know this best themselves." Tudor Edwards's home life was a happy one: a boy-and-girl friendship became a life-long devoted union.

His remains were interred in a country churchyard looking out over the waves towards that principality which has cradled not a few of those who have initiated, advanced, and adorned the thoracic surgeon's art. There Tudor Edwards "sleeps under the wings of Renown."

A colleague in the R.A.F. writes:

With the passing of Tudor Edwards the Royal Air Force has lost one of its very good friends. Early in the war he was appointed consultant in thoracic surgery to the R.A.F., but before this he had done much unselfish and often entirely gratuitous work for members of the Service. There are many present and past members of the R.A.F. walking about to-day who will hear of his death with deep regret, for they owe their good health and often their lives to his wonderful skill and care.—A. F. R.

Dr. HENRY W. P. YOUNG died on Aug. 15 in Streatham, where he had gone to live after retirement at the end of 1945. He settled in Norbury 45 years ago after a brilliant career at Cambridge, where he went with an exhibition to Caius College, taking a first in the Natural Sciences Tripos. Going to St. Bartholomew's Hospital, he qualified M.R.C.S., L.R.C.P. in 1896, and M.B., B.Ch. in 1897, proceeding to M.D. in 1901. After sundry appointments he settled in Norbury, then a small offshoot of Streatham, where he passed the remainder of his professional life. Shy and somewhat reserved, he gained the confidence of his patients, and in that young and growing district he soon held a commanding position in maternity work and children's illnesses. Painstaking and thorough, he never seemed to tire, and was always happiest when the work was hardest. In the first world war he joined partnership with a colleague in order to "do his bit" and in 1918 he returned with an added zest. Most careful in all his work, he was a first-rate diagnostician and his clinical judgment was seldom at fault. His health broke down in 1927, and he underwent an abdominal operation, but in three months he was back at work, and never slackened till, in 1945, he began to tire easily, and later in that year had the first of two serious operations, the second taking place two months later. Growing weaker, he recognized that he would be unfit for further active practice, and he retired at the end of that year. Dr. Young joined the B.M.A. 43 years ago, and was twice married. The constant care of his wife, a trained nurse, eased the burden of his last days. Much sympathy has been expressed for her in her bereavement.

FREDERICK WILLIAM BRODERICK, who died at Bournemouth on Aug. 19, was born in South Africa on Oct. 6, 1881, the second son of George Broderick. He qualified L.D.S.Eng., M.R.C.S., L.R.C.P. in 1905 after serving an apprenticeship with the late Mr. Dancer Whittles of Birmingham. After qualification he entered partnership with the late Mr. Stephen Coxon at Wisbech. While in practice there he read for and in 1912 was called to the Bar. In 1913 he moved to Bournemouth, where he established himself in practice. At the outbreak of the 1914 war he obtained a commission in the R.A.M.C. and was immediately posted over-seas to the B.E.F., obtaining thereby the Mons Star. He was invalided home in April, 1915. The Dental Services then were in chaos, and he was soon given the task of organizing them in the Southern Command, being the first dental inspecting officer appointed, with the rank of major. He it was who originated the first central dental laboratory, requisitioning part of the Birmingham Dental Hospital. On the cessation of hostilities he returned to practice in Bournemouth. There he immediately became immersed in a problem that had always interested him: the causation of caries and pyorrhoecia. He first postulated the theory that these were opposite and distinct diseases, and on this theory he worked till the day of his death; indeed a communication from his pen on this subject has appeared in a very recent number of the *British Dental Journal*. His work on these lines has been perpetuated in his book *Dental Medicine*. It may truthfully be said that he had a transatlantic reputation, for he gave at their request an extended series of lectures to various United States Universities. Though everyone may not agree with his ideas *in toto*, few will be found to say that he was entirely wrong in his conception. Much more work is required on this subject, but it may well be found that he has sown a train of thought which may bear great fruit. He died in 1910 Marion Leach, of Wisbech, and is survived by a son, and two daughters.

ELLA G. A. WEBB, who died on Aug. 25, was the widow of G. R. Webb, Fellow of Trinity College, Dublin. A daughter of Charles T. Ovenden, D.D., she was born in Dublin on Oct. 16, 1877, and went to school at Queen's College, Harley Street, London, and at Alexandra College, Dublin. In 1896 she entered the Catholic University of Ireland and won honours and an exhibition when graduating B.A. in 1899, and again when taking her medical degrees in 1904; she proceeded M.D. in 1906. Dr. Webb had been demonstrator of physiology in the Women's Department of the Medical School of Trinity College and also at the Medical School of the Catholic University before being elected to the visiting staff of the Adelaide Hospital as assistant physician to the Children's Department; she also held other medical appointments in Dublin. Her chief interest was paediatrics, and she carried out several pieces of research on rickets and other diseases of childhood. She was lady district superintendent of the St. John Ambulance Brigade at the outbreak of war in 1914 and was awarded a medal for her gallantry during the Sinn Féin Rebellion in 1916. Her work for first-aid was recognized by appointment as M.B.E. and Lady of Grace of the Order of St. John of Jerusalem.

The sudden and tragic death of Dr. JOHN FORBES CAMPBELL removes from the Totton and Southampton area a greatly respected and popular member of the medical profession. Born in 1892 at Auchenblae, Kincardine, he was educated at the Mackie Academy, Stonehaven. He obtained his dental and medical qualifications in Edinburgh in 1916 and 1917 respectively, and for a time worked at the Royal South Hants and Southampton Hospital. Joining the R.A.M.C., he carried out useful work in Mesopotamia and Persia during the first world war. On demobilization he took up general practice in Totton, and during his very busy career he earned the devotion of his patients and the respect of his medical colleagues, and his never-failing good humour and generosity gained him many friends. Despite the calls of a busy practice he found time to take a leading part in the work of the St. John Ambulance Brigade and the British Legion. In connexion with the latter he acted as the president of the Totton branch of the Legion since its inception eleven years ago. He was also hon. surgeon to the Fenwick Cottage Hospital, Lyndhurst, and medical officer to the Government Training Centre at Redbridge. He was a member of the Southampton Division of the B.M.A. and of the Southampton Medical Society. Dr. Campbell was a fine clinician, and his wide knowledge and broad outlook on life enabled him to be the generous friend and adviser to the many who sought his advice. Too busy to indulge in much social activity he obtained some relaxation from his work in an occasional game of golf. His partners and friends will ever remember his unfailing cheerfulness, kindness of character, and his skill as a raconteur. In 1930 he married Dr. Laurel Heny, and to her his medical colleagues extend their deep sympathy in her immeasurable loss.—S. N. L.

The following tribute to Dr. HOWARD HENRY, M.C., comes from Mr. Gilbert Ranson, Clerk of the East Suffolk County Insurance Committee: My committee has learned with sorrow of the death of Dr. Henry. He joined the committee's medical list when he returned to Suffolk in 1926. He was appointed by his colleagues to represent them on the committee in 1931. He so identified himself with the work, serving on most sub-committees, that he was appointed vice-chairman in 1941 and held that office until his death. He was also chairman of the Panel Committee, and in his dual position he was always ready to try to smooth out any difficulties that arose. Though he lived twelve miles from the committee's office and had a large country practice, he seldom allowed more than a week to elapse without visiting me, when he was prepared to discuss any medical questions. He probably shortened his life by undertaking, during the war, most of the work of an absent colleague along with his own. He was most assiduous in seeing that this practitioner received all that was due to him under the Protection of Practices Scheme. He has left a gap which it will be difficult for the committee to fill.

SIR KAYE LE FLEMING: MEMORIAL SERVICE

A memorial service for Sir Kaye Le Fleming, held in Wimborne Minster, was very largely attended. The service was conducted by his brother Canon Hugh Le Fleming, assisted by the head master of Canford School and the Rev. J. Mahon, priest-in-charge of the Minster. The British Medical Association was represented by Dr. S. Watson Smith, past President, Dr. J. A. Pridham representing the Council and the Dorset and West Hants Branch of the B.M.A. and the Dorset Panel and Insurance Committees, with Mr. John Whittingdale, chairman of the West Dorset Division, and many other colleagues and friends.

Dr. O. C. CARTER, of Bournemouth, gave an address of remembrance, in the course of which he said that though they mourned the death of their friend they thanked God for his life, devoted to healing the sick and guiding his profession through many of the difficulties which had arisen in the past 40 years. His own close friendship with "E. K." (as he was affectionately known) and all the help and kindness he received during nearly 30 years would be a cherished memory. Sir Kaye Le Fleming was an outstanding man of his time and would have made a success in whatever walk of life he had pursued; but instead of devoting his energy, great ability, and leadership to his own advantage, he spent his life in the interests of his fellow men. Dr. Carter, in a tribute to Sir Kaye's many-sided career, said that he was a man of striking personality and presence, with the lawyer's clarity of mind and eloquence of speech. He stood out among a small group who played

PENICILLIN

is for the **PRACTITIONER** to use

Penicillin *Glaxo* does not demand such special technique or precautions that its use is practicable only in a hospital. Nor are repeated minimal injections essential to its success—the individual dose can in most cases be increased, and frequency of injection diminished, with safety and advantage. Because Penicillin *Glaxo* is completely non-toxic the practitioner can freely use it to clear up quickly such everyday infections as boils, carbuncles, whitlows, streptococcal tonsillitis, nasal sinus infections, early otitis media and many similar conditions. Where the indications are clear the results are invariably excellent. Penicillin *Glaxo* for injection averages 75 % pure penicillin

PENICILLIN *Glaxo*

Dry sodium salt for injection in aqueous solution
Supplied in vials of 100,000; 200,000; 500,000, and 1 mega (1,000,000) units.
ONLY INJECTION OF PENICILLIN B.P. and PENICILLIN LOZENGES B.P.
are also available.

Manufacturers of **PENICILLIN**

GLAXO LABORATORIES LTD. GREENFORD, MIDDLESEX. BYRON 3434

PENICILLIN LOZENGES—M&B

PENICILLIN LOZENGES—M & B are designed for the oral treatment of all infections of the mouth and throat which are known to be caused by organisms sensitive to Penicillin notably Vincent's infection.

Each lozenge contains 500 international units of Penicillin (Calcium Salt) in a special lozenge base. They will retain their potency for approximately four months under ordinary cool conditions, and longer when refrigeration is possible.

Containers of 50 lozenges.

"Isn't there something I can take, doctor?"

Pretty often-heard question in these days of food shortages. The majority of the questioners probably do feel a real need to 'take something'.

Fortunately for those whose chief trouble is lack of calories, fats and vitamins, there is now no shortage of pure cod liver oil. SevenSeaS' trawlers have been back on the job for some time, so there is plenty of SevenSeaS cod liver oil in the chemists' shops for all who need it—both liquid oil and capsules.

For some time we have been trying, through advertising, to make people realise that our sea-fresh cod liver oil is a highly nutritious fatty food—the only one available in sufficient quantity to make good the cut in the fat ration, for example. Moreover, it is the only natural source of concentrated vitamins (A and D) which is both home-produced and plentiful. We are giving as much publicity as possible to these facts, in the hope that our efforts may in some measure help the public to combat the effects of continued "belt-tightening".

STANDARD OIL: Vitamin A 20,000 I.U.; Vitamin D 2,500 I.U. per oz.
CONCENTRATED: Vitamin A 60,000 I.U.; Vitamin D 6,000 I.U. per oz.

One successful method of infant feeding alone can compete (in antiquity) with the Sphinx. Doubtless, when the latter at last succumbs to Time, breast feeding will still remain the unchallenged method of laying the foundation of health and vigour. For more than 40 years Cow & Gate Milk Food has provided a reliable and effective substitute when breast feeding proves impossible. It can therefore claim to have been "Tested by Time" even though this is measured in years rather than in centuries. During this period the application of increased knowledge of infant requirements and of process refinements has been continuous. The two standard foods in the Cow & Gate range are as follows:—

FULL CREAM

This food is found to be of suitable composition for the great majority of normal infants. It conforms approximately to the fat content of average breast milk. It is prepared from finest quality milk powder produced under carefully controlled conditions to ensure closest possible uniformity of quality. It contains 320 I.U. vitamin D per oz. and 1 mg. of iron per oz.

HALF CREAM

When foods other than breast milk are first introduced, some children require a reduced fat intake. In a smaller number of cases it is advisable to continue with the lower fat content for several months. The Half Cream food, which contains the same vitamins and iron supplements as the Full Cream variety, has this reduction of fat and addition of carbohydrate in the form of milk sugar.

Particulars of these and other Cow & Gate preparations for specialised infant feeding, will be gladly forwarded on request.

GUILDFORD SURREY

decisive part in guiding the medical profession through the changing years after the first great war. It was in 1912 that he became a leader in local committees during the inception of the National Health Insurance Act. He always fought for the interests and welfare of insurance patients, at the same time maintaining the honour and dignity of the profession. He never lost sight of the fact that the interests of the patient and those of the doctor were identical. In his own Division he was a pillar of strength and a wise and friendly counsellor. In 1922 he was elected to the Central Council of the B.M.A. It soon became evident that his was the voice of a leader, and by the middle of that decade he was marked for high office. He became chairman in succession of the Panel Conference, the Representative Body, and the Central Council. As a chairman Le Fleming was outstanding: he was a master of procedure, long and difficult agendas were disposed of with the utmost efficiency and attention to detail, and when he spoke everyone listened. After mentioning Sir Kaye's many public activities and distinctions Dr. Carter said that it was the personal attributes he had in such large measure which made him an outstanding success as a leader of his own profession. His charm of manner attracted men to him and his great gift of fellowship won him a wide circle of friends. He had great power of concentration and an unusual degree of foresight and of vision of things to come, and his boundless capacity for work and an orderly mind got things done. His propelling force was the desire to help his fellows and forget himself, and this he did not only for those around him but in a wider sphere. The high example he set, and the affection in which they all held him, would ever live in their hearts.

Universities and Colleges

SOCIETY OF APOTHECARIES OF LONDON

At a recent meeting of the Court of Assistants, with Dr. H. F. Powell, Master, in the chair, Dr. Christopher Thackray Parsons was elected Master, and Dr. John Prescott Hedley and Prof. E. C. Dodds, Wardens, for the ensuing year.

Prof. Dodds was appointed to represent the Society at the British-Swiss Medical Conference at Basle, Sept. 16-21, and Sir Cecil Wakeley on the governing body of the British Postgraduate Medical School and the British Postgraduate Medical Federation.

It was unanimously resolved that the Society's Gold Medal in Therapeutics for 1946 be awarded to Sir Alexander Fleming and Sir Howard Florey in recognition of their discovery of penicillin.

The resignation of Mr. W. T. Withers, Bedel, who entered the service of the Society in Feb., 1887, was received with profound regret. It was decided to record on the minutes the unanimous expression of the Court's deep appreciation of his unswerving loyalty, devotion to duty, and the outstanding value of his work to the Society during nearly sixty years. Mr. E. J. Dearman was appointed Bedel to the Society from Sept. 1.

The Diploma in Industrial Health was granted by examination to the following candidates: A. Anderson, K. Biden-Steele, M. P. Fitzsimons, O. G. Bennett, G. F. Keatinge.

The Diploma of L.M.S.S.A. was granted upon examination to the following candidates: F. W. Flight, D. Rivers, C. M. M. Severn, P. R. Needham, I. T. Holloway, A. Macarthur, F. Deutscher, D. A. Bailey, H. Walker, G. Steinberg, R. Cartledge, W. F. Belsham, J. M. Jones, C. C. Gibbons, R. N. H. Vann, R. M. Michelmores, R. M. Jenkins, E. J. Rich, A. Culiner, J. L. Struan-Marshall, K. R. W. Müller.

The Services

Surg. Cmdr. H. T. Rylance, R.N.V.R. (ret.), has been awarded the R.N.V.R. officers' decoration.

Major D. C. Bowie, O.B.E., R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in the defence of Hong Kong in 1941.

17th London British General Hospital.—The reunion dinner will be held at Oddenino's Restaurant, Piccadilly, on Oct. 25. Information and tickets can be obtained from Dr. C. H. Atkinson, 53, Park Street, London, W.1; Dr. D. Batchley, 2 Chatsworth Road, Chiswick, W.4; Dr. S. P. Rea, 84, Banstead Road, Carshalton, Surrey.

Medical News

On Oct. 4 the Scottish members of the B.M.A. are making a presentation to Dr. R. W. Craig, O.B.E., to signalize his retirement from the position of Scottish Secretary. A reception and dance will be held at B.M.A. House, 7, Drumsburgh Gardens, Edinburgh, which all subscribers are invited to attend. Each subscriber may bring one guest. The cost of a single ticket will be 12s. 6d. and a double ticket one guinea.

The British Red Cross Society has established its own Department of Welfare Service. This Department is concerned with the extension of welfare and aftercare services to distressed or disabled members of the civilian community. Dr. Harold Balme, F.R.C.S., medical officer in charge of rehabilitation to the Ministry of Health, has been appointed director of welfare services. These will operate in three main directions: (a) welfare services and aftercare for civilian disabled; (b) the aftercare of invalid and crippled children, in co-operation with the Central Council for the Care of Cripples, the Invalid Children's Aid Association, and similar bodies; (c) the welfare of aged infirm. A conference on welfare service to be held at Gas Industries House, Grosvenor Crescent, S.W., on Sept. 25 and 26 will open the campaign for the winter months. Air Marshal Sir Harold Whittingham, K.C.B., K.B.E., F.R.C.P., has recently been appointed medical adviser to the British Red Cross Society.

The Fuel Efficiency Committee of the Ministry of Fuel and Power has arranged for a conference on "Fuel and the Future" to be held in London on Oct. 8-10, 1946. The Minister of Fuel and Power, Mr. Emanuel Shinwell, will open the proceedings on the first day, and the Minister of Health will speak on "The Fuel Requirement of the Housing Programme." Delegates will be mainly concerned with the use of fuel in industry, but on the afternoon of Oct. 8 Prof. James Mackintosh, Dean of the London School of Hygiene, will discuss comfort in the home in relation to human needs.

Mr. John N. Barron, formerly director of the UNRRA plastic surgery unit, Belgrade, will discuss medical problems of rehabilitation in Yugoslavia on Wednesday, Sept. 11, at 5.30 p.m., at 4, Spanish Place Mansion, Manchester Square, W., under the auspices of the British-Yugoslav Association.

The Oral Surgery Club hopes to start its post-war activities early in 1947. Members who have changed their addresses during the war should notify the Hon. Sec., Mr. R. S. Taylor, at 88, Portland Place, W.1.

Concern is felt at the shortage of midwives in Scotland. The Department of Health for Scotland has recently issued a circular suggesting the recruitment of midwives who have withdrawn from practice for personal reasons. By taking up part-time or spare-time work they would help to relieve the permanent staffs at present hard-pressed by the increase in the birth-rate. Preferential delivery of motor-cars for the use of domiciliary midwives may be requested. Local authorities are reminded that they can still make an order under Defence Regulation 33 to enable a midwife who has surrendered her certificate to resume practice.

The British Association for the Advancement of Science has arranged a two-day conference to be held at the Institution of Civil Engineers, Great George Street, London, S.W., on Sept. 12 and 13, when experts will speak on the general problems of traffic, town planning and architecture, and on the special problems of roads, railways, underground railways, and travel by air. Full details can be had from the office of the British Association at Burlington House, Piccadilly, W.1.

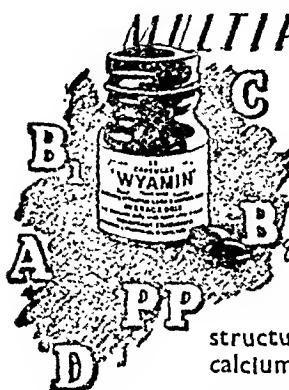

The Inter-departmental Committee on Scientific Instruments has appointed a Panel to investigate the surgical and dental instruments industries. The Panel will recommend what should be done to encourage development of the industries, to increase production, and to put the industries on a sound economic basis. Manufacturers who wish to assist the Panel by supplying information should apply to: The Secretary, Surgical and Dental Instrument Panel, Room 507, Portland House, Tothill Street, London, S.W.1.

According to the *Times* (Aug. 14) a vast black market company trading in penicillin, with ramifications in Asia, Europe, and America, is believed to have been discovered by the American authorities in Berlin. Narcotics and penicillin are listed as among the chief articles traded.

The August issue of *New Braille* includes an article on Health and Fitness by Dr. Ethel Browning.

The annual meeting of the American Public Health Association will be held in Cleveland, Ohio, in the week beginning Nov. 11. Representatives from every State and from Canada and the countries of South America are expected. It will be the first full-scale meeting since January, 1942.

MULTIPLE VITAMIN THERAPY

Upon the presence in sufficient quantity of the major vitamins depends the healthy functioning of nerve tissues, skin and other epithelial structures and bone, and normal calcium absorption.

He became chairman in succession of the Panel Conference, the representative Body, and the Central Council. As a chairman Le Fleming was outstanding: he was a master of procedure, long and difficult agendas were disposed of with the utmost efficiency and attention to detail, and when he spoke everyone listened. After mentioning Sir Kaye's many public activities and distinctions Dr. Carter said that it was the personal tributes he had in such large measure which made him an outstanding success as a leader of his own profession. His charm of manner attracted men to him and his great gift of fellowship won him a wide circle of friends. He had great power of concentration and an unusual degree of foresight and of vision of things to come, and his boundless capacity for work and an orderly mind got things done. His propelling force was his desire to help his fellows and forget himself, and this he did not only for those around him but in a wider sphere. The high example he set, and the affection in which they all held him, would ever live in their hearts.

Universities and Colleges

SOCIETY OF APOTHECARIES OF LONDON

At a recent meeting of the Court of Assistants, with Dr. H. F. Powell, Master, in the chair, Dr. Christopher Thackray Parsons was elected Master, and Dr. John Prescott Hedley and Prof. E. C. Dodds, Wardens, for the ensuing year.

Prof. Dodds was appointed to represent the Society at the British-Swiss Medical Conference at Basle, Sept. 16-21, and Sir Cecil Wakeley on the governing body of the British Postgraduate Medical School and the British Postgraduate Medical Federation.

It was unanimously resolved that the Society's Gold Medal in Therapeutics for 1946 be awarded to Sir Alexander Fleming and Sir Howard Florey in recognition of their discovery of penicillin.

The resignation of Mr. W. T. Withers, Bedel, who entered the service of the Society in Feb., 1887, was received with profound regret. It was decided to record on the minutes the unanimous expression of the Court's deep appreciation of his unswerving loyalty, devotion to duty, and the outstanding value of his work to the Society during nearly sixty years. Mr. E. J. Dearman was appointed Bedel to the Society from Sept. 1.

The Diploma in Industrial Health was granted by examination to the following candidates: A. Anderson, K. Biden-Siele, M. P. Fitzsimons, O. G. Bennett, G. F. Keatinge.

The Diploma of L.M.S.S.A. was granted upon examination to the following candidates: F. W. Flight, D. Rivers, C. M. M. Severn, P. R. Needham, I. T. Holloway, A. Macarthur, F. Deutscher, D. A. Bailey, H. Walker, G. Steinberg, R. Cartledge, W. F. Belsham, J. M. Jones, C. C. Gibbons, R. N. H. Vann, R. M. Michelmores, R. M. Jenkins, E. J. Rich, A. Culiner, J. L. Struan-Marshall, K. R. W. Miller.

The Services

Surg. Cmdr. H. T. Rylance, R.N.V.R. (ret.), has been awarded the R.N.V.R. officers' decoration.

Major D. C. Bowie, O.B.E., R.A.M.C., has been mentioned in dispatches in recognition of gallant and distinguished services in the defence of Hong Kong in 1941.

17th London British General Hospital.—The reunion dinner will be held at Oddenino's Restaurant, Piccadilly, on Oct. 25. Information and tickets can be obtained from Dr. C. H. Atkinson, 53, Park Street, London, W.1; Dr. D. Batchley, 2 Chatsworth Road, Chiswick, W.4; Dr. S. P. Rea, 84, Banstead Road, Carshalton, Surrey.

Medical News

On Oct. 4 the Scottish members of the B.M.A. are making a presentation to Dr. R. W. Craig, O.B.E., to signalize his retirement from the position of Scottish Secretary. A reception and dance will be held at B.M.A. House, 7, Drumsheugh Gardens, Edinburgh, which all subscribers are invited to attend. Each subscriber may bring one guest. The cost of a single ticket will be 12s. 6d. and a double ticket one guinea.

The British Red Cross Society has established its own Department of Welfare Service. This Department is concerned with the extension of welfare and aftercare services to distressed or disabled members of the civilian community. Dr. Harold Balme, F.R.C.S., medical officer in charge of rehabilitation to the Ministry of Health, has been appointed director of welfare services. These will operate in three main directions: (a) welfare services and aftercare for civilian disabled; (b) the aftercare of invalid and crippled children, in co-operation with the Central Council for the Care of Cripples, the Invalid Children's Aid Association, and similar bodies; (c) the welfare of aged infirm. A conference on welfare service to be held at Gas Industries House, Grosvenor Crescent, S.W., on Sept. 25 and 26 will open the campaign for the winter months. Air Marshal Sir Harold Whittingham, K.C.B., K.B.E., F.R.C.P., has recently been appointed medical adviser to the British Red Cross Society.

The Fuel Efficiency Committee of the Ministry of Fuel and Power has arranged for a conference on "Fuel and the Future" to be held in London on Oct. 8-10, 1946. The Minister of Fuel and Power, Mr. Emanuel Shinwell, will open the proceedings on the first day, and the Minister of Health will speak on "The Fuel Requirement of the Housing Programme." Delegates will be mainly concerned with the use of fuel in industry, but on the afternoon of Oct. 8 Prof. James Mackintosh, Dean of the London School of Hygiene, will discuss comfort in the home in relation to human needs.

Mr. John N. Barron, formerly director of the UNRRA plastic surgery unit, Belgrade, will discuss medical problems of rehabilitation in Yugoslavia on Wednesday, Sept. 11, at 5.30 p.m., at 4, Spanish Place Mansion, Manchester Square, W., under the auspices of the British-Yugoslav Association.

The Oral Surgery Club hopes to start its post-war activities early in 1947. Members who have changed their addresses during the war should notify the Hon. Sec., Mr. R. S. Taylor, at 88, Portland Place, W.1.

Concern is felt at the shortage of midwives in Scotland. The Department of Health for Scotland has recently issued a circular suggesting the recruitment of midwives who have withdrawn from practice for personal reasons. By taking up part-time or spare-time work they would help to relieve the permanent staffs at present hard-pressed by the increase in the birth-rate. Preferential delivery of motor-cars for the use of domiciliary midwives may be requested. Local authorities are reminded that they can still make an order under Defence Regulation 33 to enable a midwife who has surrendered her certificate to resume practice.

The British Association for the Advancement of Science has arranged a two-day conference to be held at the Institution of Civil Engineers, Great George Street, London, S.W., on Sept. 12 and 13, when experts will speak on the general problems of traffic, town planning and architecture, and on the special problems of roads, railways, underground railways, and travel by air. Full details can be had from the office of the British Association at Burlington House, Piccadilly, W.1.

The Inter-departmental Committee on Scientific Instruments has appointed a Panel to investigate the surgical and dental instruments industries. The Panel will recommend what should be done to encourage development of the industries, to increase production, and to put the industries on a sound economic basis. Manufacturers who wish to assist the Panel by supplying information should apply to: The Secretary, Surgical and Dental Instrument Panel, Room 507, Portland House, Tothill Street, London, S.W.1.

According to the *Times* (Aug. 14) a vast black market company trading in penicillin, with ramifications in Asia, Europe, and America, is believed to have been discovered by the American authorities in Berlin. Narcotics and penicillin are listed as among the chief articles traded.

The August issue of *New Braille* includes an article on Health and Fitness by Dr. Ethel Browning.

The annual meeting of the American Public Health Association will be held in Cleveland, Ohio, in the week beginning Nov. 11. Representatives from every State and from Canada and the countries of South America are expected. It will be the first full-scale meeting since January, 1942.

Dr. Syed Hassan Alavi, Director of a department of the Iranian Army Medical Service, is visiting this country to renew contacts with London hospitals, and to study the administration of the Ministry of Health and the R.A.M.C.

The Ministry of Labour has appointed a blind man, Mr. A. E. Wilson, to be senior temporary assistant of its Disabled Persons Branch in London. He is a native of Lincolnshire and an expert on blind welfare.

Mr. Geoffrey Parker, D.S.O., F.R.C.S., has been appointed a Chevalier de la Légion d'Honneur and awarded the Croix de Guerre, with Palm.

The Queen recently opened a new plastic surgery centre at St. Barnabas's Hospital, East Grinstead, Sussex. £100,000 has been contributed to the cost by the British War Relief Society of America.

EPIDEMIOLOGICAL NOTES

Typhoid Epidemics

The combined incidence of typhoid and paratyphoid was the largest for five years although the notifications of typhoid decreased by 36. Cases of typhoid notified at Aberystwyth during the four weeks ending Aug. 17 were 1, 54, 48, and 19. The largest return for any other area during this period was 8 for Warwickshire. There have been no new cases at Aberystwyth over the past week, and there were altogether 135 notifications with 4 deaths up to Sept. 3. A few cases in returned holiday-makers are still being reported from other areas. Cardiff City Isolation Hospital has admitted 1 case and there is 1 case at the Belper Isolation Hospital and 1 at Port Talbot.

At Coatbridge, Lanarkshire, as in the Aberystwyth epidemic, an ice-cream vendor who was a typhoid carrier was responsible for the recent outbreak. By Sept. 4 there were 105 cases under observation, most of them children.

Outbreaks of Paratyphoid

More information is now available about the 22 cases of paratyphoid infected at Woolacombe between June 26 and July 9. In the opinion of the M.O.H. 19 of these cases were infected by contaminated ice-cream. The other cases may have been infected while bathing near a sewer which opens into the sea. The organism responsible was found in samples of sea-water taken near the outfall and in the sewage tanks, which have since been chlorinated.

There are now 17 cases of paratyphoid in the North Staffordshire area, 11 in Stoke-on-Trent and 6 in Newcastle. There appears to be no common cause for these or for the earlier cases in this area.

Yorkshire West Riding has had 37 notifications (Halifax C.B. 25) and there have been 23 other cases of paratyphoid widely distributed throughout the country.

Discussion of Table

In *England and Wales* there were increases in the number of cases of whooping-cough 187 and paratyphoid fever 47, and decreases in the notifications of measles 587 and typhoid fever 36.

The increase in cases of whooping-cough was mainly confined to the northern section of the country. The largest rises were Warwickshire 50, Yorkshire West Riding 35, and Lancashire 25.

The sixth consecutive week there have been fewer notifications of measles. The largest falls during the week were Essex 95, Durham 94, and Lancashire 65.

The only alterations of any size in the local trends of diphtheria were decreases in London 11 and Durham 9. The largest returns of cases of dysentery were London 13 and Lancashire 12.

In *Scotland* a rise of 11 was recorded in the notifications of diphtheria, dysentery, and whooping-cough, while a fall was recorded for measles 38. The rise in diphtheria was contributed by the western area. Dundee had 12 and Glasgow 11 cases of dysentery.

In *Eire* the notifications of diphtheria increased by 7. Of the 44 cases of diarrhoea and enteritis 37 were recorded in Dublin C.B.

Week Ending August 24

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 665, whooping-cough 2,058, diphtheria 285, measles 2,140, acute pneumonia 299, cerebro-spinal fever 39, acute poliomyelitis 30, dysentery 52, paratyphoid 66, typhoid 36.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 17.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the total are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Letters, Notes, and Answers

communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: Aitology Vestcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Articulate, Westcent, London. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association. TELEPHONE: EUSTON 2111. TELEGRAMS: Medisecra Westcent, London.

M.A. SCOTTISH OFFICE: 7, Drumshough Gardens, Edinburgh.

ANY QUESTIONS?

Blood Sugar Level

Q.—Is the blood sugar level for a fasting individual a constant for that individual? At the same number of hours after two exactly similar meals is the blood sugar level the same?

A.—The blood sugar level for a fasting individual is not always the same but may vary within the normal limits of 80 to 120 mg. per 100 ml. of blood. It depends on the individual's general state of health, and may be on the low side of normal, say, just after a holiday, and on the high side of normal when a holiday is needed. It may vary slightly from this and similar causes, but in general varies little from day to day.

Prognosis in Prematurity and Immaturity

Q.—Does the prognosis in a premature infant differ from that in an immature infant? If so, in what way?

A.—The terminology is perhaps unfortunate. Because of difficulties in determining the precise length of gestation in many instances, the term "premature" is loosely used when what is really meant is "immature." By definition, for the purpose of comparison of records, the standard taken is 5½ lb. (2,500 g.) or less. On this weight standard it will be found of course that the prognosis is invariably proportional to the weight. The more immature the functions of the baby—i.e., if it has difficulty in breathing, or digestion, or maintaining body temperature—the less chance it has of survival. The premature baby born accidentally is usually better able to survive than that born prematurely (especially by induced labour) of a mother with a toxæmia. To sum up, the more immature the baby the worse the prognosis. Immaturity can be roughly gauged on the weight standard irrespectively of the degree of prematurity based on the estimated duration of gestation.

Fly-proofing with D.D.T.

Q.—What is the most efficient method of fly-proofing a room with D.D.T.? Should it be applied to the whole area of walls and ceiling and furniture to be effective? What are the effective concentrations, and what vehicle should be used?

A.—The cheapest and most effective way of using D.D.T. to fly-proof a room is to apply it as a 3 to 5% spray in kerosene. The 5% spray will be slightly more effective, but it can be prepared only with crude kerosene: refined, "odourless" kerosene will not dissolve more than about 3%. Certain recent tests have suggested that D.D.T. deposits are slightly irritant to flies and mosquitoes, and that they may not settle for long periods on treated surfaces. Therefore it seems undesirable to rely on small treated patches, for the flies may not rest on them long enough to acquire a lethal dose. It is therefore probably best to spray the ceilings, lamps, and hanging fixtures, and the upper third of the walls. Polished furniture should not be sprayed with a kerosene solution for obvious reasons. The method of use of D.D.T. against house-flies is fully described in an article by P. G. Stock and J. R. Busvine in *Monthly Bulletin of the Ministry of Health and E.P.H.L.S.*, p. 147, July, 1945.

Mushroom and House Pests

Q.—(i) What is the nature of the small grub often found in field and cultivated mushrooms burrowing into the head? Is there any risk in eating stewed or fried mushrooms which may have hidden in them any of these small grubs?

(ii) Are there any handy books on household pests—beetles, cockroaches, wood-lice, fleas, silver fish, earwigs, clothes moths?

A.—(i) The small grubs found in mushrooms are larvae of the mushroom midge *Sciara* spp. of the family Mycetophilidae. These larvae would be killed by the heat of stewing or frying, so there should be no actual danger from eating cooked mushrooms.

(ii) There does not seem to be a very comprehensive treatise on domestic pests published in this country, but *Domestic Pests*, by L. Hunter (J. Bale and Sons, London, 1938, 7s. 6d.), is a fairly good elementary handbook. The inquirer is reminded that the British Museum (Natural History) produces a very good series of pamphlets dealing with most of the pests to which he refers.

Corporal Punishment in Schools

Q.—What is the law concerning corporal punishment in schools? I am frequently consulted by parents whose children attend schools where they may be caned or slapped by a "teacher." The schools in question are council schools, and the parents are economically unable to remove their children. Has any other adult, having temporary charge of a child, right to administer such punishment? If none exists, can such teachers be restrained by law?

A.—Physical correction in the classroom has never been regarded as a common assault *per se*, and the court will always inquire whether in the particular circumstances the amount and nature of the force used were reasonable. This therefore would be the issue whether the parent charged the teacher in the magistrates' court or sued him in the county court. The best plan in practice would be for the parent to write to the county education officer. The local education authority would in all probability investigate the complaint seriously, withholding the name of the complainant; for quite apart from its conception of what is fitting it would not willingly invite the publicity of litigation. Neither the authority nor the court, however, would be likely to concede that physical correction should be unconditionally forbidden.

Protein Digest Material

Q.—(i) Of what value is protein digest material in treating gastric ulcers and pre- and post-operative partial gastrectomies?

(ii) Using the ordinary post-operative partial gastrectomy régime, would a protein digest be irritable to the stomach at a time when a Ryle's tube may be in use to prevent accumulation of fluid, or when alternate hourly feeds with sterile water and citrated milk are the only other foods by mouth?

A.—(i) American work, particularly that emanating from Co Tui, appears to indicate that protein digests fed orally hasten recovery. Apart from the buffering effect, it is difficult to see what advantage this method of treatment offers over administration of intact protein in bland foodstuffs. Even in a partial gastrectomy there should be sufficient digestive power remaining in the other parts of the alimentary canal to obviate any pre-treatment of a hydrolytic nature. Clinical evidence supports the view that under hospital care ulcers heal rapidly.

(ii) There is no real indication for the administration of a protein digest in the circumstances described. Protein digests are not very palatable, and on that account might upset the patient.

Excessive Granulation Tissue

Q.—How often should excessive granulation tissue be treated with silver nitrate? Is this the best treatment for a discharging umbilicus in a babe aged 4 weeks, where granulation tissue covers the lesion?

A.—If excessive granulation tissue continues to form after two or three applications of silver nitrate there must be some

special cause hindering healing, and further investigation is needed. Granulation tissue at the umbilicus in a babe of four weeks may simply be due to delayed healing of the stump of the umbilicus. Sometimes a small granuloma the size of a raspberry may form and require removal. In other cases there may be a persistent portion of the vitelline duct or of the urachus beneath the granulation tissue. In any case of doubt a surgeon experienced in diseases of children should be asked to see the patient.

Desensitizing Solutions. Insecticides

Q.—(i) *What is the technique of preparing desensitizing solutions of horse-hair, dust, etc., for administration to allergic patients, and the correct dosage?*

(ii) *D.D.T. has been hailed as the most efficient means of disinfection. Why does liberal sprinkling of the inside of my trousers twice in twelve hours with 5% D.D.T. powder not cause cessation of flea activity? I find pyrethrum, at present unobtainable, to be more efficacious.*

A.—(i) The processes involved in the preparation of "desensitizing" solutions for horse-hair and house dust are defatting, extracting, filtering, sterilizing, and testing for sterility, while evaporating and sterilizing may be desirable. The detailed technique for all the common allergens is excellently presented by Leon Unger in *Bronchial Asthma*, pp. 627-39 (Charles C. Thomas), together with the dilutions used for intradermal testing.

The initial dose in treatment is 0.1 ml. of the dilution which just fails to give a positive skin reaction. The injections are at first given twice a week and later once a week. The dose is increased by 50% until local reactions occur and then by 30%.

The danger of severe constitutional reactions when using horse-hair extracts must be fully realized, especially when assessing the initial dose, and when the larger doses are being given. It is advisable to do scratch tests first and only to do intradermal tests with a dilution which is negative on scratch testing; while when the larger doses are being given the increases should be about 15%. The maximum dose is about 1 ml. of 1 in 100 solution, but this depends on the degree of sensitivity, and the maximum dose is that at which the patient is improved. House dust rarely causes severe constitutional reactions, and the maximum dosage is about 1.0 ml. of the 1 in 10 solution. It is usually advisable to continue house dust injections for from six to eighteen months, depending on the response of the patient.

(ii) Pyrethrum kills fleas immediately, while D.D.T. does not kill immediately and will not prevent individual bites. Powders are available in which both D.D.T. and pyrethrum are incorporated.

Menopausal Hypertension

Q.—*Is endocrine therapy of any benefit in menopausal hypertension?*

A.—Most but not all observers claim that menopausal hypertension responds to oestrogen therapy, and it is claimed that in such cases the systolic pressure can be reduced by as much as 35 to 50 mm. Hg. At the menopause, however, the blood-pressure can undergo considerable variations spontaneously, so it is not always easy to judge the effect of treatment. A relatively small dose (e.g., oestrone, 0.1 mg. t.d.s. by mouth, 0 mg. twice weekly by injection) is said to be sufficient an effect.

INCOME TAX

Employment of Assistant

R. W. inquires as to the effect on taxation of the two alternative methods of paying an assistant, (a) at a salary of £x, with free use of surgery premises for residential purposes, and (b) at a salary of £x+£y, out of which the assistant is required to pay £y as rent of such premises. The premises are owned by R. W.

* * R. W. can in either case claim the expense he incurs. In (a) he can deduct £x and also the amount at which the premises are assessed to income tax under Schedule A. In (b) he can claim to deduct £x+£y as an expense, but must account for tax not only on the

Schedule A assessment but also (under Schedule D) on the excess of £y over that amount—less some allowance for repairs. Broadly, therefore, R. W. will receive the same deduction whichever alternative he adopts. But that is not the case as regards the assistant. Under alternative (a) the assistant would be liable for tax on £x only; under (b) he would be liable on £x+£y.

Cost of Postgraduate Course

D. S. asks whether instances can be cited of the admission of the cost of a postgraduate course having been allowed for income tax purposes.

* * No. In general a postgraduate course is taken to improve or extend professional knowledge, and as such the cost would be regarded as an outlay of capital rather than an expense of the practice. If the course were a "refresher" course there would be some grounds for contending that the cost should be allowed on the analogy of the replacement of medical textbooks with more up-to-date editions.

Married Woman in Industry

J. M. is married and is fully employed as an assistant medical officer in a factory. Is she entitled to the relief given to married women in industry?

* * Yes—i.e., the special allowance of £110 for 1946-7. (The corresponding amount for 1945-6 was £80.)

LETTERS, NOTES, ETC.

D.D.T. Preparations

Dr. A. LEWIS (London, W.9) writes: There are a number of firms selling D.D.T. in the form of a spray for household use. One firm admitted on the label that the strength of their spray was only 0.5%. I inquired about the strength of other makes and found that those who would admit their figure at all also gave it as 0.5%. This is surely an inadequate amount, and it is probably based on a fear that a proper 5% solution might be absorbed by the skin with toxic effects. It should be pointed out that this is extremely unlikely in ordinary household use, and that the inadequate strength at present being sold is liable to bring a valuable substance into disrepute.

Swallowed Kirby Grips

Prof. CHARLES WELLS (Liverpool) writes: I was interested in the question and answer (Aug. 3, p. 184) about Kirby grips swallowed by children. Very often these get held up in the second part of the duodenum, being unable to negotiate the difficult double turn and cross the vertebral column to enter the jejunum. In children there is a minimum of fatty padding around the duodenum and kidney, and I believe that a Kirby grip coming to rest in this situation should be removed without waiting too long. When the operation is undertaken it is best to pass the Kirby grip back into the stomach, if possible, before taking it out.

Daffodil Dermatitis

Dr. P. E. S. PALMER (Hayle) writes: With reference to the question and answer on daffodil dermatitis (June 15, p. 940), may I refer your questioner to the article in the *Lancet* (1934, 2, 755) on this subject by Palmer, W. H., and Freeman, J., and express surprise that whoever answered your question could not have referred to one of the standard textbooks—*Common Skin Diseases*, by A. Roxburgh, London, 1944—in which this article is quoted. It contains a satisfactory method of prevention of this very troublesome condition.

The fourteenth report of the Memorial Ophthalmic Laboratory at Giza, Cairo, covers the five years 1939 to 1944. It contains a selected list of publications by the staff, together with a list of papers not included in this report. J. O. W. Bland, in a review on the aetiology of trachoma, attempts to bridge the gap between the contending supporters of a rickettsia origin and a virus origin of the affection. R. P. Wilson gives a useful survey on the significance of the acute ophthalmias in Egypt, and together with Bland discusses the value of the sulphonamides and penicillin. There are several other papers dealing with the chemotherapy of the acute ophthalmias and of trachoma. Egyptian workers do not seem to have found the sulphonamides effective in trachoma, but there is no indication that they have tried intensive local therapy. They are enthusiastic on the value of the sulphonamides administered orally in the acute ophthalmias, and rather dismiss penicillin as a local therapy, though there is no evidence that they have tried this out in a suitable concentration and suitable frequency. The report also contains a short paper on schistosomiasis of the conjunctiva, and another one on leishmaniasis of the eyelid, both by Ahmed Kamel.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 7 1946

British Medical Association COUNCIL AND COMMITTEES FOR 1946-7

COUNCIL

EX OFFICIO

Mr. Hugh Lett, Bt., Richmond, *President*.
Dr. J. B. Miller, Bishopbriggs, Lanarkshire, *Chairman of Representative Body*.
Dr. H. Guy Dain, Birmingham, *Chairman of Council*.
Dr. J. W. Bone, Luton, *Treasurer*.
Dr. E. A. Gregg, London, *Deputy Chairman of Representative Body*.
Mr. H. S. Souttar, London, *Immediate Past President*.

TWENTY-TWO ELECTED BY BRANCHES IN THE UNITED KINGDOM England and Wales:

Dr. J. A. Brown, Birmingham.
Mr. L. Dougal Callander, Doncaster.
Dr. E. C. Dawson, Derby.
Dr. H. M. Golding, Bristol, 5.
Dr. F. Gray, London.
Dr. W. V. Howells, Swansea.
Dr. J. A. Ireland, Shrewsbury.
Mr. R. Kennon, Liverpool.
Dr. C. G. Martin, London.
Mr. A. M. A. Moore, London.
Dr. D. R. Owen, Chester.
Dr. J. A. Pridham, Weymouth.
Dr. C. M. Stevenson, Cambridge.
Dr. H. H. D. Sutherland, London.
Dr. J. G. Thwaites, Brighton.
Dr. N. E. Waterfield, Little Bookham.
Mr. Weldon Watts, Newcastle-upon-Tyne.

Scotland:

Dr. P. Martin-Brodie, Edinburgh.
Dr. Mary Esslemont, Aberdeen.
Dr. I. D. Grant, Glasgow.
Dr. G. MacFeat, Douglas, Lanarkshire.

Northern Ireland:

Mr. C. J. A. Woodside, Belfast.

EIGHT ELECTED BY BRANCHES NOT IN THE UNITED KINGDOM

Dr. J. H. Anderson, Ruthin (*South Australian, Tasmanian, Victorian, and Western Australian Branches*).
Dr. Isaac Jones, London (*New South Wales and Queensland Branches*).
Col. J. J. Harper, Nelson, Isle of Mull (*Indian Group*).
Mr. A. E. Porritt, London (*New Zealand and Fiji Branches*).
Dr. P. T. O'Farrell, Dublin (*Cannought, Leinster, Managhan and Cavan, Munster, and South Eastern of Ireland Branches*).
3 vacancies.

TWELVE ELECTED BY GROUPED REPRESENTATIVES

England and Wales:

Dr. O. C. Carter, Bournemouth.
Dr. R. W. Cockshut, London.
Dr. H. R. Frederick, Port Talbot.
Mr. A. Staveley Gough, Watford.
Dr. J. A. L. Vaughan Jones, Leeds.
Mr. R. L. Newell, Cheadle.
Dr. A. Talbot Rogers, Bromley, Kent.
Dr. S. Wand, Birmingham.
Mr. A. Dickson Wright, London.

Scotland:

Dr. W. D. Frew, Kilmarnock.
Mr. I. Simson Hall, Edinburgh.

Northern Ireland:

Dr. J. M. Hunter, Portrush.

EIGHT ELECTED BY REPRESENTATIVE BODY

Mr. A. Lawrence Abel, London.
Dr. J. C. Arthur, Low Fell.
Prof. A. H. Burgess, Cheadle, Cheshire.
Dr. W. E. Dorman, Sheffield.

Dr. R. Forbes, London.
Dr. Peter Macdonald, York.
Dr. A. Smith Pool, Glasgow.
Dr. W. D. Steel, Worcester.

TWO ELECTED BY PUBLIC HEALTH SERVICE MEMBERS

Dr. J. Fenton, London.
Dr. R. H. H. Jolly, Wolverhampton.

SERVICE REPRESENTATIVES

Surg. Rear Admiral W. H. Edgar, Alverstoke (R.N.M.S.).
Major-Gen. R. W. D. Leslie, Nottingham (R.A.M.C.).
Air Marshal Sir Victor Richardson, Gerrards Cross (Medical Branch of R.A.F.).
Major-Gen. R. H. Candy, London (I.M.S.).

ONE WOMAN ELECTED BY WOMEN MEMBERS

Dr. Janet K. Aitken, London.

COMMITTEES

1. STANDING COMMITTEES

(Note: The President, Chairman of Representative Body, Chairman of Council, and Treasurer are members, *ex officio*, of all Standing Committees.)

CENTRAL ETHICAL COMMITTEE

1 member to be appointed by the General Practices Committee.
1 member to be appointed by the Hospitals Committee.
With power to co-opt three additional members.

SCIENCE COMMITTEE

Mr. A. Lawrence Abel, London.
Prof. R. S. Aitken, Aberdeen.
Mr. V. Zachary Cope, London.
Sir Henry H. Dale, London.
Dr. R. G. Gordon, Bath.
Mr. R. Kennon, Liverpool.
Dr. R. P. St. L. Liston, Tunbridge Wells.
Mr. L. S. Pyrah, Leeds.
Mr. H. S. Souttar, London.
Dr. C. C. Ungley, Newcastle-upon-Tyne.

SCOTTISH COMMITTEE

Members of Council:

Dr. P. Martin Brodie, Edinburgh.
Dr. Mary Esslemont, Aberdeen.
Dr. W. D. Frew, Kilmarnock.
Dr. I. D. Grant, Glasgow.
Mr. I. Simson Hall, Edinburgh.
Dr. G. MacFeat, Douglas, Lanarkshire.
Dr. A. Smith Pool, Glasgow.

23 Members elected by Divisions in Scotland:

Dr. J. C. Adam, Forres.
Mr. R. L. Beveridge, Dumfries.
Dr. J. Inglis Cameron, Glasgow.
Dr. W. Leslie Cuthbert, Stirling.
Dr. Wm. Gibson, Old Kilpatrick.
Dr. Kate Harrower, Glasgow.
Dr. J. M. Johnstone, Leven.
Dr. J. F. Lambie, Glasgow.
Dr. D. Dale Logan, Newmains.
Dr. K. McLay, Galashiels.

Dr. A. F. Wilkie Millar, Edinburgh.
Dr. D. Myles, Forfar.
Mr. Robert Richards, Aberdeen.
Dr. G. A. Rorie, Dundee.
Dr. A. Scott, Ayr.
Dr. J. G. Shand, Culter.
Dr. J. T. Simpson, Perth.
Dr. C. W. Somerville, Bonnyrigg.
Dr. A. E. Struthers, Paisley.
Dr. John Young, Edinburgh.
3 vacancies.

The President, Royal College of Physicians, Edinburgh.

The President, Royal College of Surgeons, Edinburgh.

1 member to be nominated by Royal Faculty of Physicians and Surgeons of Glasgow.

With power to co-opt not more than two.

WELSH COMMITTEE

Members of Council representing Branches in Wales and Monmouthshire:

Dr. A. W. Anderson, Ogmore Vale.
Dr. D. E. J. Burke, Newport.
Dr. Tudor Williams, Pontypridd.
Dr. Oscar Williams, Llanelly.
Dr. Emrys D. Owen, Neath.
With power to co-opt not more than 2.

II. GROUP COMMITTEES

ANAESTHETISTS GROUP COMMITTEE

(Shortly to be elected)

DERMATOLOGISTS GROUP COMMITTEE

London:

Dr. G. W. Bamber.
Dr. G. Duckworth.
Dr. L. Forman.
Dr. A. C. Roxburgh.

Provinces:

Dr. F. F. Hellier, Leeds.
Dr. R. M. B. Mackenna, Liverpool.
Dr. C. H. Whittle, Cambridge.

Scotland:

Dr. J. Ferguson Smith, Glasgow.

Northern Ireland:

Dr. I. H. McCaw, Belfast.

FULL TIME NON-PROFESSORIAL MEDICAL TEACHERS, LABORATORY AND RESEARCH WORKERS GROUP COMMITTEE

(Shortly to be elected)

OPHTHALMIC GROUP COMMITTEE

13 Members directly elected by Members in Regions:

Dr. W. A. Anderson, Belfast.
Mr. George Black, Leeds.
Sir Stewart Duke-Elder, London.
Mr. J. P. J. Evans, Birmingham.
Dr. N. P. R. Galloway, Nottingham.
Dr. J. J. Healy, Llanelly.
Dr. E. G. Mackie, Sheffield.
Dr. J. Marshall, Glasgow.
Mr. O. Gayer Morgan, London.
Mr. A. McKie Reid, Liverpool.
Mr. F. Oliver Walker, Dartford.
Mr. M. H. Whiting, London.
Dr. David Wilson, Torquay.

2 elected by Non-Members of Group engaged in N.O.T.B. Work:

Dr. R. G. Simpson, London.
Dr. C. M. Stevenson, Cambridge.

6 appointed by the Council of the Faculty of Ophthalmologists:

Mr. R. Affleck Greaves, London.
Mr. E. F. King, London.
Mr. Frank W. Law, London.
Dr. W. Niccol, Gloucester.
Dr. Doris Rose, Derby.
Dr. J. N. Tennant, Glasgow.

1 appointed by the Council of the Association:

Dr. R. H. Balfour Barrow, Winchester.

ORTHOPAEDIC GROUP COMMITTEE

(Shortly to be elected)

PATHOLOGISTS GROUP COMMITTEE

(Shortly to be elected)

PHYSICAL MEDICINE GROUP COMMITTEE

(Shortly to be elected)

PSYCHOLOGICAL MEDICINE GROUP COMMITTEE

(Shortly to be elected)

RADIOLOGISTS GROUP COMMITTEE

(Shortly to be elected)

SPA PRACTITIONERS GROUP COMMITTEE

(Shortly to be elected)

III. OTHER COMMITTEES

BUILDING COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).
Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
Dr. J. W. Bone, Luton (*Treasurer*).
Mr. L. Dougal Callander, Doncaster.
Dr. O. C. Carter, Bournemouth.
Mr. A. Staveley Gough, Watford.
Dr. C. G. Martin, London.
Mr. A. M. A. Moore, London.
Dr. J. G. Thwaites, Brighton.
Mr. A. Dickson Wright, London.

COMPENSATION AND SUPERANNUATION COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
Dr. G. F. Buchan, London.
Dr. R. W. Cockshut, London.
Dr. E. A. Gregg, London.
Dr. J. A. L. Vaughan Jones, Leeds.
Dr. A. T. Rogers, Bromley.
Dr. S. Wand, Birmingham.

EX-SERVICE PRACTITIONERS COMMITTEE

Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
Dr. E. A. Gregg, London.
Dr. S. Wand, Birmingham.
Mr. R. L. Newell, Cheadle.
Dr. P. Martin Brodie, Edinburgh.
Dr. R. G. Gordon, Bath.
Dr. A. Talbot Rogers, Bromley.
Dr. J. Fenton, London.
With power to co-opt ex-Service practitioners.

FILM COMMITTEE

Dr. A. E. Barclay, Oxford.
Dr. J. A. L. Vaughan Jones, Leeds.
Dr. R. P. St. L. Liston, London.
Dr. G. G. Macgrath, Liverpool.
Dr. R. C. MacKeith, Southampton.
Mr. R. L. Newell, Cheadle.
Mr. H. Reid, Liverpool.
Dr. C. M. Seward, Exeter.
Prof. J. C. Spence, Newcastle-upon-Tyne.

Mr. A. Dickson Wright, London.
The Rt. Hon. Lord Amulree, London.
Prof. G. P. Meredith, Exeter.
Chairman, Science Committee.
Representatives of the British Medical Students' Association.

SPECIAL G.M.C. COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).
Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
Dr. J. W. Bone, Luton (*Treasurer*).
Dr. E. A. Gregg, London.
Dr. N. E. Waterfield, Little Bookham.
Dr. Frank Kane, Cork.
Dr. R. W. Craig, Edinburgh.
Dr. Robert Forbes, London.
Dr. Richard W. Durand, London.
Prof. Henry Cohen, Liverpool.
Dr. W. E. Dorman, Sheffield.
Dr. James Fenton, London.
Dr. Thomas Fraser, Aberdeen.
Dr. W. D. Frew, Kilmarnock.
Dr. Annis Gillie, London.
Mr. R. Kennon, Liverpool.
Major R. W. D. Leslie, London.
Mr. A. M. A. Moore, London.
Dr. J. G. Thwaites, Brighton.
Mr. A. Dickson Wright, London.
Dr. H. B. Morgan, M.P., London.

INTERNATIONAL RELATIONS COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
 Dr. J. W. Bone, Luton (*Treasurer*).
 Dr. Alfred Cox, London.
 Dr. John Clayre, Southampton.
 Dr. S. C. Dyke, Wolverhampton.
 Dr. J. L. Gilks, Petersfield.
 Dr. N. Howard Jones, London.
 Dr. J. C. Matthews, Downton.
 Dr. J. A. Pridham, Weymouth.
 Dr. S. Laurie Smith, St. Annes-on-Sea.
 Dr. G. de Swiet, London.
 Dr. N. E. Waterfield, Little Bookham.
 Chairman of Dominions Committee.
 Chairman of Journal Committee.
 Mr. T. A. Madden, British Medical Students' Association.

MEDICAL CURRICULUM COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
 Dr. J. W. Bone, Luton (*Treasurer*).
 Dr. Janet K. Aitken, London.
 Prof. Henry Cohen, Liverpool.
 Mr. V. Zachary Cope, London.
 Dr. Anthony Feiling, London.
 Dr. R. G. Gordon, Bath.
 Dr. F. Gray, London.
 Dr. E. A. Gregg, London.
 Dr. G. MacFeat, Douglas, Lanarkshire.
 Mr. R. L. Newell, Manchester.
 Prof. L. G. Parsons, Birmingham.
 Dr. F. M. Rose, Preston.
 Mr. I. Simson Hall, Edinburgh.
 Prof. Sidney Smith, Edinburgh.
 Mr. H. S. Souttar, London.
 Dr. J. G. Thwaites, Brighton.
 1 Representative of British Medical Students' Association.

PARLIAMENTARY ELECTIONS COMMITTEE

Sir Hugh Lett, Bt., Richmond (*President*).
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).

 Together with representatives of the Magistrates Association.

THE NEGOTIATING COMMITTEE

16 Representatives of the B.M.A.:

Sir Hugh Lett, Bt., Richmond (*President*).
 Dr. J. B. Miller, Bishopbriggs (*Chairman of Representative Body*).
 Dr. H. Guy Dain, Birmingham (*Chairman of Council*).
 Dr. J. A. Brown, Birmingham.
 Dr. F. Gray, London.
 Dr. E. A. Gregg, London.
 Mr. R. L. Newell, Cheadle, Cheshire.
 Dr. S. Wand, Birmingham.
 Dr. P. Martin Brodie, Edinburgh.
 Dr. J. F. Lambie, Glasgow.
 Dr. A. T. Rogers, Bromley.
 Dr. J. A. L. Vaughan Jones, Leeds.
 Dr. G. H. Sedgwick, Rotherham.
 Dr. J. C. Arthur, Low Fell.
 Dr. S. A. Winstanley, Urnston.
 Dr. R. W. Cockshut, London.

- 3 *Representatives of Royal College of Physicians:*
Lord Moran, London.
Dr. H. E. A. Boldero, Stanmore.
Prof. Henry Cohen, Liverpool.
- 3 *Representatives of Royal College of Surgeons:*
Sir Alfred Webb-Johnson, London.
Mr. V. Zachary Cope, London.
Vacancy.
- 2 *Representatives of Royal College of Obstetricians and Gynaecologists:*
Mr. Eardley L. Holland, London.
Mr. A. A. Gemmell, Liverpool.
- 3 *Representatives of Royal Scottish Medical Corporations:*
Prof. C. McNeil, Edinburgh.
Sir Henry Wade, Edinburgh.
Dr. J. H. Macdonald, Luss.
- 2 *Representatives of Society of Medical Officers of Health:*
Dr. G. F. Buchan, London.
Dr. R. H. H. Jolly, Wolverhampton.
- 1 *Representative of Medical Women's Federation:*
Dr. Mary Esslemon, Aberdeen.
- 1 *Representative of Society of Apothecaries:*
Dr. H. Seward Morley, Midhurst.
- 1 *Representative of Association of Honorary Staffs of Major (Non-undergraduate Teaching) Voluntary Hospitals of England and Wales:*
Mr. H. J. McCurrah, Hove.

is representing 52,000 members of the profession, and is painstakingly trying to ascertain the wishes of its members, and of those non-members who are willing to let it represent their views. The motion as re-drawn by Dr. R. W. Cockshut of Hendon, "That in the view of this Representative Meeting no registered medical practitioner should accept membership of any committee or board established under the National Health Service Act, until the results of the forthcoming plebiscite are available," became an expression of opinion on an important ethical matter by an overwhelming majority of the R.B. And I would here mention Dr. Guy Dain's wise statement earlier in the meeting: "It is continually put to me that it may be that this Representative Body does not represent the profession. For my part, I am prepared to stand by the decisions of this Body! We are not prepared to believe that the representatives come here, and vote for things—as they did last May—for which they have no authority in their constituencies." And finally, may I point out that, among the four decisions taken in May, decisions which appear to make a conflict with the Minister of Health inevitable, was one which declared, by a vote of 210 to 29, that the S.R.M. was opposed to the State ownership of hospitals?—I am, etc.,

VICTOR RUSSELL,
Chairman, S. Staffs Division, B.M.A.

Wolverhampton.

SIR,—Dr. Frank Bodman deplores the passage of the amendment outlawing the Regional Boards. Does he not realize that the only way in which the medical profession can compel the Government to alter the proposed National Health Service is for them to be united absolutely in their refusal to serve on any board, council, or committee? The Act could not then be put in force. We have a good example of what result this sort of action can produce in the iron and steel industry.—I am, etc.,

Farnham.

G. HUMPHRY WARD.

Correspondence

The Representative Body and Regional Boards

SIR,—I read with interest and some amusement Dr. Frank Bodman's letter (Aug. 24, p. 69). As the "opportunistic hot-head with a persuasive tongue" who talked the R.B. round into voting against its better judgment, I should like to say that—vastly though I am flattered by this tribute to my supposed powers—I am not conspicuously hot-headed, and that I brought this matter up on the specific instruction of my Division and with the support of all my group, which represents an entire county.

Obviously, Dr. Bodman was not present at the A.R.M., and equally obviously he is one of those who are in favour of accepting invitations from the Minister of Health to serve on his administrative bodies—before the profession has decided whether it will work the Health Service Bill or not. If the majority of the profession expresses itself in favour of working the Bill, that will be the time for its members to entertain such invitations. Those who are in such a painful hurry to accept invitations now would not only prejudice our entire position before the profession's collective will had been expressed but would lay themselves open to the suspicion that they were hastening to climb on to the Ministry's band-wagon in the hope of stealing a march on more scrupulous colleagues. At all events, since the profession's decision will probably be known in November, why this haste on the part of a few to ingratiate themselves with the Minister?

The "antic behaviour" of the A.R.M., at all events in this instance, was conspicuous by its absence. The amendment was quietly and carefully discussed—very few, if any, representatives being absent—and when it was thought advisable to alter its form and present it as a motion the necessary three-quarters majority for a suspension of Standing Orders was obtained, and when the motion was put to the vote it was carried by a majority of about eight to one, with few, if any, abstentions—and that, whether Dr. Bodman likes it or not, is democracy in operation!

No. Dr. Bodman's complaints just will not do. He leaves no doubt that he disapproves of what happened, and even that he feels personally sore about it, but he does contrive to leave a doubt as to whether he would consider himself bound, regarding professional policy, by an overwhelming vote of his colleagues.

To conclude, Dr. Bodman asks if the B.M.A. is to legislate for every medical practitioner. It is not legislating at all, but it

SIR,—Dr. Frank Bodman's witty criticism of the Representative Body (*Supplement*, Aug. 24, p. 69) raises an important and urgent problem. Is the present machinery of the R.B. efficient? I confess that my experience as a delegate for the past five years suggests that the R.B. is unwieldy, verbose, and swayed by the able and eloquent tongue of the present Chairman of Council, Dr. Dain.

Do the delegates express the majority view of their colleagues, whom they represent? I wonder! I was elected together with my fellow delegates from Birmingham at a full meeting of the profession to consider the report of Council. Rarely are there more than thirty doctors present. The apathy of the rank and file is the unknown quantity that must be overcome now or else we shall surely drift into a National Health Service the conditions of which we shall have had no part in implementing. For a brief period during the war years the study groups were started to discuss matters of importance and forward their views back to headquarters. Can this method be introduced now? I doubt it. But it might be well worth while to ask this direct question through the local Branches: Are you in favour of the Negotiating Committee discussing terms and conditions of service or not? Leave it to local secretaries to determine the best way to make contact with all their members, and perhaps an answer might be obtained. At all events it could not be worse than the present appalling position in which loyal members of the B.M.A. are debarred from serving on Regional Boards on account of a resolution passed by an R.B. exhausted by a mass of motions and amendments, the speakers to which are rarely able, often dull and prosaic, and always, if given a chance, long-winded and pointless.

As a result it is with a feeling of relief the delegates listen to the Chairman of Council, and the spontaneous cheers from all present are in part due to the sporting instinct of the members appreciating a good stroke even if it fails to score. Dr. Dain has laid stress on the united vote of the R.B. against the purchase and sale of practices, and there can be no doubt that he places his hopes of a successful battle with the Government on these majorities.

This period of uncertainty must cease and only the Council of the B.M.A. can bring this about. The National Health Bill has now passed through the House of Commons, with little or no change since the first reading. The Government was not

impressed with arguments raised against the controversial parts by the leaders of the medical profession, and what is more important it has been stated all too often by members of the Government that the profession as a whole is not with its leaders. There lies a challenge. It is up to the Council of the B.M.A. to find out the true answer, and find it out now, or cease to lead.—I am, etc.,

Birmingham

R. C. L. BURGESS.

N.H.I. Capitation Fee

SIR,—The Insurance Acts Committee and the Spens Report both agree that the capitation fee should have been 12s. 6d. in 1939 and 15s. now. Considering the additional burdens placed upon us during the war years, many of which we still bear, and the ever-increasing costs of living and running a practice these figures are on the low side. We have been grossly underpaid for many years and unless we assess our work at its real value and insist on being paid accordingly we shall go on being underpaid, and this would be detrimental to the profession, to our patients, and ourselves.

Now the Minister of Health magnanimously tells us that he will increase the fee to 12s. 6d., retrospective from Jan., 1946. One can assume that if we agree to this it will again be our fee under the coming National Medical Service, and if this assumption is near the mark the sooner we show a united fighting front the better for the future of the profession. Instead of discussing if we will accept service under the National Medical Service why not let the Minister of Health see now that we can act as a united body and refuse to accept inadequate remuneration under the N.H.I. at present?

I suggest that under the leadership of the B.M.A. and the M.P.U. we tender our resignations under the N.H.I. as from April 1 next if the Minister does not agree to a capitation fee of 15s. retrospective from Jan., 1946, and also that this figure applies only to the N.H.I. and that the fee under the N.H.S. be discussed later when more details of conditions of service are known to us. If we allow this incident to slide by we shall regret our weakness. Surely we have been dilatory enough in the past in pressing our just claims for adequate remuneration. Let us act without further delay.—I am, etc.,

Wetherby.

S. T. PYBUS.

Ethics of Contract Medical Practice

SIR,—As a practitioner of thirteen years' experience who has for the first time in his life come in contact with panel practice, I was very interested to read Dr. A. G. Badenoch's article on the ethics of contract medical practice (Aug. 17, p. 63). Few will dispute his views as applied to panel practice in England; but there are other types of contract practice to which his criticisms do not apply.

Before the war I was a member of a firm of British medical practitioners practising in a foreign city in a sub-tropical country. The practice consisted mainly of British employees of the local municipal council, public utilities, and commercial firms, with which contracts were arranged, the principle being recognized that the employer was responsible for the medical care of his employees.

Our contracts covered the medical care, at office and home hospital, of all from boss to office boy, divided into three e-groups—viz., up to £500 p.a.; £500–£1,000; over £1,000 p.a. The average fee was £2–£3 p.a. Extras were operations, midwifery, anaesthetics, and courses of intravenous injections. These were also at standard rates, operations being classified as (a) major; (b) minor with general anaesthetic; (c) minor with local. The rates for these extras were similarly scaled according to income and were very reasonable, about £25 being the average fee for a major operation.

Any doctor wishing to operate this scheme was almost necessarily obliged to practise "group medicine." Our firm comprised two F.R.C.S.(Eng.), one M.D., M.R.C.P., one M.D., D.P.H., D.T.M.&H., and two M.B., B.S. Each member did his share of the general practice and specialized in some branch, referring his cases to the appropriate partner. The two main hospitals catering for European patients were open to all recognized practitioners and three classes of accommodation were provided according to income groups, as well as free wards maintained by the municipal council.

Competition was keen, there being at least three firms practising group medicine and able to provide a comprehensive service. No sense of inferiority was engendered in the patients as everyone was in it from boss to office boy; all patients were treated with the same consideration, as a row over the office-boy could easily lead to cancellation of the entire contract.

From the practitioners' point of view, the scheme was nearly ideal. He felt he was well rewarded for his labours and, being able to live off fewer patients at higher rates than the panel, was able to give better individual attention. He could follow his cases right through hospital and the operating theatre in conjunction with his colleagues. He was kept mentally alert and keen to develop a specialty. He was not continuously harassed by considerations of the patients' pockets, though any tendency to extravagance was checked by possibility of losing the contract. Any misunderstandings or complaints could be expeditiously dealt with over the telephone or by personal contact; there was no amorphous and anonymous Ministry to deal with.

The patients' benefits were obvious. General and specialist attention given by doctors personally known to them; freedom from worry over medical bills; confidence inspired by the stress on preventive medicine, so necessary in a sub-tropical climate (routine smallpox vaccination, T.A.B., and cholera inoculations were given annually, and periodic inspection of places of work and homes were included in the contract. Classes of instruction in first-aid, sick nursing in the home, etc., were held for scouts, guides, women's institutes, etc.). Self-employed and retired individuals were also allowed to enter into contracts for themselves and families at the same rates. Private patients were few and were mostly visitors or temporary residents.

In the course of thirteen years' practice in three continents, I have never met a more stimulating or harmonious atmosphere of general practice. Critical ability of the patients was high and a high standard of proficiency was expected from their doctors. Competition with Continental and transatlantic colleagues brought out the best and most progressive; while intimate contact with the public health authorities, mission doctors, laboratory and research workers, through a very active medical society, gave one a sense of satisfaction and fulfilment, so different from the deadening drudgery, the hardening of heart and narrowing of interest, which remain the lot of too many panel doctors in England.—I am, etc.,

Henley-on-Thames.

I. G. ANDERSON.

Medical Unemployment

SIR,—I feel that I must join issue with those practitioners who are complaining of difficulty in finding employment on their release from the Services. I have been seeking an assistant, with or without a view, or a partner since February, 1945. I have interviewed at least 50 men (in many cases entertaining them and their wives, some even staying the night) and have written to over 100 more and I have encountered the following difficulties:

First. No acknowledgment of my letters in at least 30 cases. Secondly. Failure to notify me that they have accepted another post after coming for interview in at least 20 cases, and in most of these I was put to the expense of sending a telegram to find out the position.

Thirdly. A standard wording in many of the letters and advertisements is "furnished house and full use of car essential." "Ex-R.N.V.R." (Aug. 24, p. 70) states, "most of us who suffered financially." Surely he realizes that most of us who were "fortunate" enough to stay at home, apart from excessive overwork, also suffered financially and we cannot afford the expense of providing furniture, house, and car, while assistants' salaries are double what they were before the war and professional fees have only increased by 20%. In spite of the Government statement on cost of living index, the cost of running a professional house is over double what it was pre-war and in many cases three times. Practically all drugs are considerably increased in price and many are subject to purchase tax. Even our telephone bill is surcharged, every letter and account we send costs twice as much, and charges for motor repairs and new or second-hand cars have reached fantastic levels.

The doctors who have applied fall into the following categories: (1) Men who try to rush a get-rich-quick deal.

(2) Those who wish to rush into partnership without any adequate consideration or investigation, presumably because I have a house available. (3) Those who cannot make up their minds. (4) Those who are insisting on some particular district and will consider no other.

To prevent misunderstanding I would point out that this is a semi-rural practice in very lovely surroundings, although only 9 to 10 miles from Birmingham centre. Incidentally, I am offering £600 p.a. plus the usual emoluments, which brings the figure to over £850 p.a. I have made every attempt to engage an ex-Service British doctor but without success. I cannot employ an invalid assistant as this is a fairly busy practice. I shall be delighted to hear from any ex-Serviceman who really wants a job. Scorning to sign myself "Weary G.P.," which I am in more ways than one,—I am, etc.,

Alvechurch.

F. HARMAN VOLLAM.

SIR,—In reply to the numerous letters from unemployed Service doctors, I feel that there are many of us who would be only too happy to offer them employment if, firstly, we were able to find them accommodation, and, secondly, if they were prepared to accept a salary comparable with that which we received prior to the outbreak of war. They must appreciate that, although all expenses in connexion with general practice have risen, we are unable to "unload" these expenses on our private patients. Furthermore they realize the meagre increase that has been offered to us for panel patients, at least half of which will be repaid to the Inland Revenue twice annually.

If I may make a suggestion to these doctors, it would be that they should expend their energies against the Minister of Health, forcing him to provide them with suitable living accommodation in preference to health centres. Most principals are able to provide working accommodation, whereas living accommodation is quite impracticable, by reason of the fact that our wives have been excessively overworked throughout the war years, and still there are no prospects of any reasonable domestic help.—I am, etc.,

Ipswich.

WILFRED KNIGHT.

Recruitment of Civilian Specialists

SIR,—During the past months we have avoided taking part in the correspondence regarding the release of Service specialists and their replacement by E.M.S. specialists. We feel, however, that the letter signed "Two Specialists" (Aug. 24, p. 69) should be answered. We presume, of course, that those of us who have served as full-time specialists in the E.M.S. are included in the category of civilians. There are many aspects of this that we could discuss but we do not wish to obscure our main argument, which is that the majority of us who entered the E.M.S. in a senior capacity at the beginning of the war were invited to do so and the initiative did not come from us either directly or indirectly. We did not at any time take steps to avoid military service. We have served between six and seven years and are now being recruited for a further two years. Those of us in our very late thirties may not be called up for a further year or so. We may therefore find that we have had to put in a minimum of eight years and quite possibly ten. We feel that, in less emotional moments, even our Service colleagues will consider this unfair.

With regard to new appointments there is an aspect of this with which Service specialists may be unfamiliar. Hospital authorities are showing a natural reluctance to appoint men who are liable to be called up. Furthermore there is no doubt that many appointments committees are giving those who are or who have been in uniform preferential treatment. One of us has had ample proof of this in recent interviews.

In conclusion may we say we sympathize deeply with our colleagues whose release is so long delayed. At the same time we feel they will agree that the solution lies rather in the latter part of their letter and in calling up those with permanent appointments to return to rather than inflicting gross injustice on men who have been on national service for many years and who, like many serving specialists, have no such permanent appointment.—We are, etc.,

TWO E.M.S. SPECIALISTS.

Financing the Young Doctor

SIR,—Much play has been made by the Minister of Health of the miserable plight of young doctors crippling themselves by debt in order to find sufficient money to start in general practice. In fact this was one of his most cogent arguments for insisting that a basic salary should be supplied at once, and that a capitation remuneration would complete the happiness of every newly qualified doctor. Having supplied the salary, the Government—or rather Mr. Bevan—then insisted that he could direct the recipient. At this stage the Government—or again Mr. Bevan—found that they "abhorred" the buying and selling of practices. And this "abhorrence" fitted in easily with the principle of a basic salary; for the possession of a private practice was not compatible with "direction" and a Civil Service salary.

Now, if the Minister of Health is truly worried and concerned about the crippling effect of young doctors borrowing money at qualification, why should not the Government offer to supply the struggling young doctor with say £2,000 to put him on his feet? Or even earlier during his medical training. This sum would be a loan repayable at some specified time, say twelve to fifteen or twenty years, and I would suggest *without interest*. The doctor would of course undertake to submit particulars of the outlay of this money to the Government, but the Government do not buy the heart and soul of the young doctor nor direct him where to settle. The Government has the satisfaction of starting a much-needed medical man serving the public with a minimum of outlay—i.e., they do not pay him £1,200 a year but start him with the wherewithal to fend for himself. The doctor has a debt, I agree, but without interest. It is not every young doctor who would need to avail himself of this scheme or borrow so much. Suppose 2,500 doctors availed themselves of this loan each year at the maximum of £2,000; that would amount to £5,000,000. This sounds a lot, but is nothing compared with £66,000,000 which Mr. Bevan is calmly taking from the public, *with nothing whatever to show for it*. This £5,000,000 is to return in good time. It is not just subsidizing the profession. It is providing the public with a body of young doctors proud and independent as every Briton should be, able to look to a future of ownership, and not worried about the difficult business terms for their loans which carry a burden of interest varying with security.

I have myself now fought through two wars, and I am heartily glad to be out of the Service for the second time and to be my own master once again in my own private practice. This sense of ownership and the feeling that one is building for the future are such a joy after six years with "no future in them." In such a State Service one cannot build. I shall lose my trusted partner, I shall lose every tangible asset which I can call my own. I resent this vehemently, particularly after six years of exile.

If Mr. Bevan is a true friend of the medical profession and truly wishes to serve his public as a Minister should he must give that public a happy, grateful, and satisfied profession. The above is one way of going to work. Intolerance, dictatorship, and mistrust appear to be the basis of the present National Health Service Bill.—I am, etc.,

Croydon.

J. W. WAYTE.

Salaries of Specialists

SIR,—Rising specialists will welcome the recommendations of the Presidents of the Royal Colleges (*Journal*, July 27). Perhaps more than anything else the position of "the 800" is due to the low salaries offered for the more senior B1 type of house job. In the *Journal* of Aug. 17 salaries of £200 per annum are offered for appointments in which preference will be given to Fellows of the Royal College of Surgeons. This of course is ridiculous, and any clerk, tradesman, or general labourer aged 30 can earn more.

An immediate improvement in the present position would occur if the Presidents of the Royal Colleges recommended a minimal salary of, say, £550 and emoluments for holders of higher qualifications and those qualified more than five years. Hospitals declining to accept these recommendations would not be recognized for F.R.C.S., M.R.C.O.G., etc.—I am, etc.,

RISING SPECIALIST.

Demobilized Specialists

SIR,—It would appear from reading the correspondence in your columns that most medical officers released from the Services have some complaints of civilian life whether they be specialists or general duty officers.

The letter from the Presidents of the Royal Colleges (*Journal*, July 27) will be welcomed by the demobilized specialist and graded specialist, but their proposals will increase the difficulties of those men who have returned after having spent their whole service as general duty officers, but who had hoped and planned to specialize had not their studies been curtailed by their call-up.

The so-called Group I referred to by the Presidents in their letter have fared much better than their contemporaries in the Services. For the most part their Service time has been spent in hospitals or in an atmosphere of clinical medicine or surgery, and now it is proposed to give them the best of both ends of the stick. The selection of specialists for training was a very haphazard affair—being in the right place at the right time and knowing the right people were often more important qualifications than clinical ability—and in the Royal Navy there was no organized training at all. If these men are to be allowed to monopolize the registrar posts until the Bill comes into force it is tantamount to closing the door to specializing to the demobilized general duty officer.

I would propose that the post of registrar should be limited to twelve months for those who have acted as graded specialists in the Services for over a year. A man should be able to obtain his higher qualification by that time. Then they should be appointed to posts as clinical assistants or salaried full-time appointments as proposed for the Group II specialists. There being such a dearth of specialists there should be no difficulty in finding or creating such appointments.

Those who were not so fortunate to receive specialist training in the Services—training which was gratis while on full pay and allowances, with the probability of increased specialist pay—should be allowed to act as registrars for two years and be paid £550 plus £100 for maintenance for the full period if they had completed 12 months as a hospital resident before call-up, or £350 plus £100 for the first 6 months and then £550 plus £100 if they only had 6 months as a resident before joining the Services. One assumes that tenure of such posts would be governed by the postgraduate deans, who would select the candidates.

I believe that these proposals would be a more just solution to one of the many problems that beset the demobilized doctor.—I am, etc.,

Wirral.

THEO L. SCHOFIELD.

H.M. Forces Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Cmdr. (Retired) N. Parry-Price to be Surg. Capt. (Retired).
Surg. Licut.-Cmdrs (Retired) R. D. Bradshaw and D. A. Imrie to be Surg. Cmdrs. (Retired).

Temp. Acting Surg. Licut.-Cmdr. S. L. Townsend to be Temp. Licut.-Cmdr.

Temp. Surg. Lieuts.: D. J. Chapman, D. Craddock, B. R. D. D. E. Jewitt, W. J. H. Lord, B. L. C. Phillips, I. B. T. Lee, R. Tringham, L. E. Wear, W. H. E. Allen, R. E. H. T. Davenport, W. J. F. Davies, J. W. L. Edwards, M. W. J. W. B. Forshaw, A. M. Fraser, R. Hierons, D. A. Knock, F. A. Lennan, N. M. Panton, E. H. Taylor, G. E. Robinson, H. B. Andrews, H. C. Ashworth, T. C. Barras, P. V. ROYAL ARMY MEDICAL CORPS

Lieut.-Col. T. L. Fraser, O.B.E., has retired on retired pay and has been granted the honorary rank of Col.

Lieut.-Col. L. S. C. Roche, M.C., having attained the age for retirement, is retained on the Active List supernumerary.

Major (War Subs. Lieut.-Col.) C. A. Levy to be Lieut.-Col.

Short Service Commissions.—War Subs. Major J. C. Babbage and Capt. T. B. Harrison have been appointed to permanent commissions.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Majors P. B. Wilkinson and P. E. C. Manson-Bahr have relinquished their commissions and have been granted the honorary rank of Lieut.-Col.

War Subs. Capt. J. R. McGregor and H. MacL. T. MacDon have relinquished their commissions and have been granted honorary rank of Capt.

War Subs. Capt. H. W. A. Baron has relinquished his commission on account of disability and has been granted the honorary rank of Capt.

War Subs. Capt. H. N. Wong has relinquished his commission.

Association Notices

Branch and Division Meetings to be Held

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Charing Cross Road, W.C., Thursday, September 12, 8 p.m., Divisional meeting. Agenda: Receive reports from Representatives to A.R.M.; consideration of formation of Study Groups to deliberate on National Health Service. 9 p.m. Dr. W. S. C. Copeman; The Rheumatic Diseases.

POSTGRADUATE NEWS

The Tuberculosis Educational Institute has arranged two refresher courses to be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C. For tuberculosis officers and medical practitioners, Sept. 23 to 28, fee, four guineas for health visitors, almoners, social workers, and chief clerks, Sept. 26 to 28, fee, ten shillings. Applications should be sent to Dr. H. Williams, Tavistock House North, Tavistock Square, W.C.1.

WEEKLY POSTGRADUATE DIARY

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Theatre, Edinburgh Royal Infirmary, Thurs., 4.30 p.m. Dr. I. G. W. H. The Electrocardiogram in Coronary Disease.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—1/8 8 p.m. Prof. W. J. B. Riddell: Irregular Dominance in Hereditary Nystagmus.

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Dr. Horsfall: Classification and Treatment of the Anaemias.

APPOINTMENTS

FISHER, R. E. W., M.B., D.P.H., Chief Medical Officer, South Metropolitan Gas Co., London.

GLoucestershire ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester. Appointments to Consulting Staff: Surgeon, A. Alcock, M.B., B.S. General Surgeon and Gynaecological Surgeon, R. L. Haines, M.R.C.S. Physicist, D. E. Finlay, M.B., B.S. Radiologist, J. Goss, M.B., B.Ch. New appointments: Surgeon and Radiology Officer, W. J. Wilkin, F.R.C.S. Surgeon and Urological Surgeon, P. M. Birks, F.R.C.S. Edin. Gynaecological Surgeon, H. A. Hamilton, M.B., M.R.C.O.G. Physician, R. F. Jarrell, M.B., M.R.C. Radiologist, E. W. Hyde, M.B., D.M.R. Assistant Surgeon to Ear, Nose and Throat Department, C. F. Evans, F.R.C.S., D.L.O. Anaesthetist, T. I. Hughes, M.R.C.S., D.A., A. Tom, M.R.C.S., D.A.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

BAGSHAW.—On August 29, 1946, at Mill Road Infirmary, Liverpool, to Jean (née Campbell), wife of H. Bernard Bagshaw, F.R.C.S. Ed., twins (girl and boy).

BRINTON.—On August 24, 1946, at Nuffield House, Guy's Hospital, to Barbara (née Lyall), wife of Dr. W. D. Brinton, 75, Victoria Road, W.8, a daughter.

BROOKER.—On August 27, 1946, at Hammersmith Hospital, to Kathleen, wife of Dr. A. E. W. Brooker, a son—John.

HILL.—On July 22, 1946, at Ayr Nursing Home, to Etta, wife of Dr. Robert Hill, G.M., M.B., Ch.B., F.R.F.P.S., a son—Christopher Robert John.

SANDILANDS.—On August 19, 1946, at Plymouth, to Cynthia, wife of James Sandilands, a son—Robert John.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Mr. A. Seymour Philips, F.R.C.S., at 104, Harley Street, W.1 (Welbeck 5900); Miss Margaret Salmond, F.R.C.S., F.R.C.O.G., at 121, Harley Street, W.1; Mr. A. H. M. Siddons, M.Ch., F.R.C.S., at 140, Harley Street, W.1 (as from Sept. 29).

LONDON SATURDAY SEPTEMBER 14 1946

POSTGRADUATE EDUCATION AND THE NATIONAL HEALTH SERVICE*

BY

Sir FRANCIS FRASER, M.D., F.R.C.P.

The Regulations governing this Lectureship state that the subject "shall be one of interest connected with medical learning science," and the selection of postgraduate medical education the subject for this occasion will, I trust, fulfil these requirements and meet with the approval of the Founder and of our college. It is a subject that has been much discussed in recent years, and it has acquired a new interest with the prospects of National Health Service in the immediate future.

Postgraduate medical education has, of course, existed as long as the profession of medicine, but it has engaged serious attention in this country in an organized form only since the beginning of this century. I do not propose to review what has been accomplished in the past, because it has been of necessity inadequate, but I must pay a tribute to the medical profession of Edinburgh, its University and the Royal Colleges, for the enterprise and efficiency of their pioneer contributions during the past forty years.

Purpose and Policies

The aim must surely be to enable each member of the medical profession, no matter what his professional field may be, to be in constant touch throughout his career with the leaders and teachers of medicine and with wiser and more experienced colleagues. His undergraduate education is designed to make him observant, receptive, and critical, to enable him to use experience that he may grow in learning and in wisdom; but he will fail to make full use of his intelligence and training unless he can share the experiences and learning of his colleagues and keep his faculties of observation and criticism always sharpened by contact with those whose role it is to educate and to instruct. There is no reason to think that this has not been the aim of all who have provided postgraduate education in the past, but it has not been possible to reach this goal for reasons which are largely economic. The public requires the help and services of doctors at all times, and the latter cannot leave their patients unless adequate replacements are available. Replacements have not been available in the past in the necessary numbers. The medical profession is fully occupied, and more, in carrying out its daily duties, and it will be necessary to expand it materially in order to free any considerable number for the pursuit of postgraduate studies. Nor have the numbers of trained and experienced teachers been adequate to enable postgraduate education to be provided on anything like the scale required. There have, of course, always been medical men, both general practitioners and specialists, who have continued to keep in touch with centres of progress and learning, but they have been a minority. In some instances this is effected by private and individual arrangements, in others advantage is taken of local organizations, and the latter are important as they afford experiences that are useful for planning on a wider scale.

In order that the Government's plan for a National Health Service, involving as it does a comprehensive service for all, may be successful a large expansion of the medical profession will be necessary in the spheres both of the general practitioner and of the specialist. This will require a number of years and involve a considerable increase in the accommodation available

in the medical schools of the country. In due course, however, there should be the numbers of experts and teachers required for postgraduate education, and there should be the necessary replacements to give every medical man the time required for his continuing education and training. The National Health Service will be based on a regional organization, each region centred for professional guidance on a University and its medical school, and composed of areas or divisions each of which will provide all the ordinary hospital and specialist services. The main divisional hospital or group of hospitals will be staffed by specialists in each of the major branches of medicine and surgery, including general medicine and general surgery, and it is largely through this staff that the necessary expansion in postgraduate education can be provided. This staff will be in constant contact, on the one hand with the teaching staffs of the University and medical school of the region, and on the other with the general practitioners of the area and the staffs of the smaller local hospitals. The professors and other teachers in the University departments should be fully occupied in the education of undergraduates and in advancing their subjects by research, and should not, except occasionally, be diverted from these essential duties to take part in postgraduate instruction; it may well be advisable for the Universities to institute chairs and departments expressly for advanced and postgraduate education in those branches of medicine and surgery that belong more especially to the postgraduate field. In London, with its peculiar circumstances of size and influence, this has already commenced and is being further developed as rapidly as possible.

The report of the Interdepartmental Committee on Medical Schools assumes that the Universities should be responsible for the development of postgraduate medical education and makes a valuable contribution to the subject. The Government has accepted this report and the Treasury and the University Grants Committee have indicated their willingness to help financially. The acceptance by the Universities of this responsibility is most welcome, for it ensures that the education provided will be of University standard. This is a vague term without any exact connotation, but surely it means that the instruction will not be merely technical and vocational, but will also be rational, co-ordinated, and cultural.

This appears to me to be of the greatest importance. There are many procedures in the practice of medicine, both in diagnosis and in treatment, that require technical skill of a high order if our patients' lives are to be saved and their health preserved. Some of these procedures can be isolated and entrusted to medical auxiliaries, others are part of more complicated procedures requiring the co-ordinated knowledge and judgment of the qualified specialist. Many fall between these extremes. There are, therefore, many essentials to successful practice that are technical, and it is tempting to fill courses of postgraduate instruction with descriptions and demonstrations of mechanical ingenuity and manual dexterity. By entrusting postgraduate medical education to the Universities this danger will, I trust, be avoided. The Nation requires from the medical profession something much more than technical skill. The individual looks to his doctor for help and guidance when his efficiency is impaired, whether the cause be spiritual or material.

* The Frederick Price Lecture for 1946 at the Royal College of Physicians of Edinburgh, July 12.

To train our doctors to this high calling, to enable them to shoulder their patients' burdens, requires teachers who by example and precept will inspire them with ideals of service and give them pride in cultural attainments as well as instruct them in professional skills. And it is to the Universities that we look to select and train the teachers we require.

We are passing through difficult times with important years of reconstruction ahead. The supply of competent teachers inspired and instructed by the older generations has been interrupted by two wars, and a National Health Service might easily produce a corps of time-servers. The maintenance of its standards is therefore a vital problem now for the medical profession, and the answer to the problem is largely an educational one and one for the medical schools to supply.

We can look forward, then, to the National Health Service providing in due course the increased number of experienced teachers and the opportunities and time for both general practitioners and specialists to attend postgraduate studies. As the plans for the new Service are developed, we must watch that they do provide what is required, for the success of the Health Service depends to a large extent on the professional standard of the medical men that will staff the Service at all levels. The need for a Service such as the Government now proposes has been questioned, and it has been suggested that the medical care of the Nation is quite satisfactory. Those who voice such opinions are, I would submit, basing their view on the condition in some particular part only of the whole, limited perhaps to locality or perhaps to a section of the profession. Those who have been concerned with the administration of the Emergency Medical Service in the war and have had an opportunity to see the standard of service available over the country as a whole are unable to agree. The knowledge and skill available for the preservation of health, the care of patients, and the treatment of disease were not accessible to large sections of the population, partly because of lack of co-ordination between the different sections of the medical services and difficulties in the pooling of resources, but largely because of ignorance on the part of medical men of what could be done and of how much better someone else with greater facilities and assistance at his disposal could serve their patients' needs. The breaking down of the barriers to the exchange of knowledge and experiences and frequent contact with centres of teaching and research should correct these faults to a large extent and improve the standard of medical practice. It will increase also the confidence of the medical profession in their ability to perform their high calling and give them cause for pride and happiness in their chosen careers. To my mind these are strong reasons why the medical profession should welcome the general principles embodied in the Government's proposals and the Nation support them; they depend on an efficient scheme of continuous postgraduate studies, and the ability of the medical schools to provide the instruction required and to realize the importance of maintaining and of raising their standards.

The report of the Interdepartmental Committee on Medical Schools has outlined the types of postgraduate education which the Committee regarded as essential and indicated briefly where they might be provided. They considered separately the training of specialists, including general physicians and general surgeons, and the postgraduate studies suited to the needs of general practitioners. They regarded the conditions in London as exceptional because of its large number of undergraduate medical schools and special hospitals, and because there was already within the University of London a medical school for postgraduate education only. The report includes recommendations for the development in London of the administrative organization required for the future. Since the publication of the report considerable progress has been made in carrying out the recommendations, and valuable experience has been acquired through providing training for specialists and for general practitioners returning to civilian practice on release from the Forces.

The Training of Specialists

It is generally agreed that the essential requirement in the training of a specialist in general medicine, general surgery, or one of their special branches is the holding of a responsible hospital appointment of the type known in different parts of the country as registrar, resident medical officer, resident surgical

officer, first assistant, chief assistant, and clinical tutor. posts are obtained after the graduate has held junior re-appointments. They are relatively few in number and the petition for them ensures that the holders have been carefully selected. The length of time during which such posts are held is not uniform and probably should not be rigidly defined. It seems to be generally agreed that a minimum period of 3 years of postgraduate training is required before a graduate can be regarded as competent for the responsibilities of a clinical specialist.

The holding of a responsible hospital appointment does of itself suffice. There must be adequate supervision by experienced teachers, one of whose duties must be to train candidates for their careers as specialists, and for this more is required than clinical material and the usual hospital environment. The duties assigned to the candidates should be sufficiently light to enable them to study their cases thoroughly. Laboratory facilities must be provided to enable them to do this, they should be encouraged by group discussions to discuss their problems and experiences, they must have ready access to libraries so that they can explore the literature of their subjects, they should be in close touch with other general special clinical departments, and it should be possible for them to spend part of their period of training working in one of the pre-clinical departments of a medical school or in a well-equipped pathological laboratory. They should be encouraged to undertake original investigations or share in the research of others, and should be given opportunities to show their aptitude for teaching. Above all they must be guided and supervised throughout their period of training. In short, the training of a specialist can be carried out only in the adequately staffed and well-equipped department of a medical school.

At present, with a few exceptions, only the undergraduate medical schools and their teaching hospitals and the University of London Graduate Medical School can provide the necessary conditions, and the appointments of the kind required at these hospitals are too few to train the specialists needed for the National Health Service and to make up for the loss of years of war, during which the number who received adequate training was below the normal pre-war figure. The release from the Forces within a period of months of many candidates for specialist careers has created an abnormal situation, and many of them have had to be appointed to hospital posts that cannot provide the necessary supervision, equipment, other facilities. The present arrangement must be recognized as an emergency measure and not as an indication of the standard that should be approved when conditions become normal once more.

The report of the Interdepartmental Committee on Medical Schools recommended that the number of appointments in teaching hospitals suitable for the training of specialists should be increased. There are ample clinical material and other opportunities for a considerable increase. Before the war the holders of these appointments were in general too busy to stop and think. Quiet thought, discussion, and reading under guidance are essentials for sound education. The number of new posts that can be created is limited by the clinical material available to properly equipped departments, but there is room for considerable expansion of University control over clinical teaching and clinical material; and the association of municipal and voluntary hospitals with the central teaching hospitals; and medical schools, as advocated by the Interdepartmental Committee, should enable still further appointments to be available for specialist training. This association should be readily accomplished under the regional system of the new health service. The different appointments will vary in the value and type of training they afford, and each will be peculiarly suited to some stage in the progress of the individual graduate. A system of transfer from one unit to another and one hospital to another should be arranged. In due course the divisional or area hospitals will be staffed by well-trained specialists from the University departments, many of them competent teachers and researchers, and a period of service at these hospitals could be included in the approved course of training. In these various ways the basic studies and practical training of the specialists required for a comprehensive service can be provided and high standards maintained.

Experience has shown that there is a need for types of instruction additional to hospital appointments for graduates entering careers in the specialties. Their provision is a problem that chiefly concerns London, but it concerns Edinburgh so to an extent that is only less in degree. Graduates from her educational centres in this country, from the Dominions, Colonies, and foreign Universities, come to London and Edinburgh, and to a lesser extent to other centres, for postgraduate study and are in many instances aiming at a higher degree or specialist diploma. They come at all stages in their training, say for varying periods, and are not necessarily seeking a full training in this country. They may plan to obtain their appointments in their own hospitals, or may be aiming at a career in general practice with one of the specialties as an additional accomplishment. For these graduates a course is required, extending over a period of about six months, which should provide the basic principles for the specialty and include lectures and demonstrations in applied anatomy and physiology and in pathology, and clinical responsibilities such as are allotted to medical clerks and surgical dressers. Such courses have been available at the Postgraduate Medical School and at certain of the special hospitals in London, and their educational value has been clearly demonstrated. By means of these courses the visitor's time is usefully occupied until he is ready to obtain a hospital appointment, and through them he becomes known to the school authorities and his suitability for appointments and for further specialist training can be assessed.

Many graduates from over-seas have already completed basic studies and obtained a practical training in their intended specialty before coming to this country. They wish to learn something of the methods, thoughts, and practice of the leaders of the profession here, and for them an advanced revision course consisting of lectures and clinical demonstrations would be invaluable. It should not be intensive, but should allow time for attendance at hospital practice and public lectures, and for reading. Such a course might extend over a period of about three months, and not only would meet the needs of the senior graduate from over-seas who is able to visit this country for a relatively short time, but would be suitable also for the graduate from this country who has completed his hospital appointments and requires his knowledge and experience revised, rounded off, and placed in proper perspective. A few such courses have been available in general medicine and general surgery, both in London and in Edinburgh, but more are required, and they should be available also in the principal special branches.

In the National Health Service there should be no difficulty in maintaining for specialists an uninterrupted connexion with centres of medical education. The regional organization will be based on a medical school, and the specialist staffs of the divisional hospitals will remain in close touch with the hospitals and teaching departments of the regional medical school. They would meet regularly at the University for discussion and for practical demonstrations, and would be encouraged to continue to advance their subjects by periods of work in the laboratories of the medical school, by co-operating in the researches of their University colleagues and by help and advice.

Further Education for General Practitioners

It may prove more difficult to provide continuous education for general practitioners. Intensive refresher courses have been offered for many years at several medical schools and have been so well attended that they clearly provide, to some extent at least, for the needs of the general practitioner. Those who attended were able as a rule to do so only at intervals of several years and were the more enlightened and progressive members of the profession. Courses of this kind were arranged on behalf of the Ministry of Health by the Postgraduate School in London shortly before the war for practitioners participating in the National Health Insurance Scheme. They were free of cost to the practitioner and allowances for travelling and maintenance and the cost of a locum tenent were authorized. At first these courses were held in London, but by the outbreak of war in 1939 the scheme had been expanded rapidly and courses had been planned in several other centres throughout the country. It was the intention that every doctor in the National Insurance Scheme should attend a course once in

three years. Shorter, intensive courses, usually on limited subjects and extending over two or three days or a week-end, were available here and there throughout the country, and they also were well attended. Courses of these types provide periodic contact only with educational centres. Experience has shown that they have considerable value, but they offer so much information in a short time that much of it is wasted and the educational value is disproportionate to the effort devoted to them by the teachers.

At some hospitals and centres, notably Newcastle-upon-Tyne, another form of contact has been practised for some years. The staff of the teaching hospital set aside one half day in each month when general practitioners visit the hospital and join in a discussion on a previously arranged subject, share in a demonstration of selected cases, or take part in a meeting of the local medical society. This more nearly fulfils the need for continuous education, but is dependent for its success on distance, transport, and other local conditions. At other hospitals similar sessions are held every week.

Each method that has been tried and found successful may well be included in the plans for the future, and it should prove easier under the National Health Service than it has in the past for the general practitioner to attend and for the teachers of experience to be available. Other methods have been suggested, and I have had opportunities of discussing them with considerable numbers of general practitioners released from the Forces who have been attending the two-weeks intensive courses arranged by the Universities under the Government scheme. As a result, I would suggest that a start be made with the following:

(i) Clinical assistantships at near-by hospitals;

(ii) One or two half-day sessions each month at the divisional hospital for meeting the hospital staff and for discussions, according to a prearranged programme;

(iii) Short courses lasting one or two days on recent progress in specific subjects at the regional medical school or teaching hospital; and

(iv) Intensive general refresher courses lasting a week or more, to be attended once a year at a centre remote from the place of practice.

(i) The clinical assistantship is the form of education that has met with the most general approval of the groups of practitioners we have consulted. It might be held for three months in the year and the practitioner would attend one or two half days a week, be assigned duties in an out-patient department, and have access to the wards of the hospital. The department to which he is attached might be a different one each year or he might prefer to concentrate on a few only. These appointments would be held at the divisional hospital or group of hospitals with their staffs of specialists, who would supervise the work and be themselves in constant touch with the regional teaching centre. This form of education could be arranged at first for practitioners in the cities and urban districts, and might be extended later to rural areas also.

(ii) The regular half-day session at the divisional hospital for meeting and discussion with the hospital staff would give the practitioner opportunities also for following the progress of his cases referred to hospital for treatment. The programme need not be confined to clinical subjects and might well include occasional discussions on administrative problems of common or local interest, on the preservation of health, and on historical or other subjects of cultural value.

(iii) From time to time new methods in diagnosis or treatment are developed sufficiently to become widely used, and it is essential that general practitioners should be informed of their possibilities and limitations. The progress in mass radiography, the use of sulphonamides, and the discovery of penicillin are recent examples. Courses of demonstrations and discussions lasting one or two days, and covering the principles as well as the practical applications of the new method, would be of great value. They should be given by experts who have been personally concerned with the development of the subject and should be conducted at the medical school of the region.

(iv) The intensive general refresher course lasting two or three weeks, and attended at intervals of several years, is not entirely satisfactory either for the practitioners attending or for the

teachers. The former are liable to suffer from mental indigestion, and the latter are frequently conscious that the time and energy they have given to preparing their demonstrations and lectures are largely wasted. I have been impressed with the opinion of a number of practitioners attending these courses that the expert in his subject who is not an experienced teacher is seldom satisfactory. And there is much truth in the suggestion that general practice is itself the most difficult of specialties, and that these courses rarely include any discussion or instruction on the common problems that concern them most. There is clearly a need for further experiment, but I have found general agreement that a week's course every year would be preferable to a longer course less often.

In order to carry out such a programme of clinical assistantships, conferences, specific short courses, and general courses of longer duration, and to provide them for all the practitioners in a region, it will be necessary to use the clinical material and the staffs of many hospitals. The undergraduate teaching hospitals cannot be expected to contribute much to these forms of postgraduate education, and the medical schools will need to enlist the co-operation of associated and divisional hospitals. It will be some years before these will be staffed on an approved basis, but a beginning can be made now and the experience gained recently in providing for the demobilized practitioners can be put to good account. The Interdepartmental Committee on Medical Schools advised the appointment of postgraduate deans or directors and a postgraduate committee in each medical school or faculty, and it would seem advisable that this should be done immediately at all Universities with medical schools, as a permanent feature in their post-war development.

The British Postgraduate Medical Federation

The conditions in London are peculiar because of the number of its medical schools, the great concentration of population and hospitals, and its position as the capital of the Empire. To make use of its unique situation in the provision of postgraduate medical education the University of London has established the British Postgraduate Medical Federation. This organization is designed to develop and co-ordinate for postgraduate education the many general and special hospitals, both voluntary and municipal, in so far as they are not required for undergraduate teaching. The aim is to develop University departments properly staffed and equipped for postgraduate students only in all the major specialties, including general medicine and general surgery. It will include from the first the Postgraduate Medical School, where University departments in general medicine, general surgery, obstetrics, and pathology have been established since 1935, and Institutes of Child Health, Laryngology and Otology, Neurology, Ophthalmology, and Psychiatry based on the schools already in existence at the special hospitals at Great Ormond Street, Gray's Inn Road, Queen Square, Moorfields, and the Maudsley Hospital. It was originally proposed that these teaching departments and institutes should be accommodated close to each other and to a central hospital or group of hospitals in a convenient and central situation in London, but this plan appears impracticable at present. A Central Office of the Federation has been established close to the University buildings in Bloomsbury and will co-ordinate to develop the scattered departments and institutes to co-ordinate their facilities for postgraduate studies. Accommodations suitable for the training of specialists will be provided at the hospitals, and courses of instruction on the lines already discussed and adapted to the specialties concerned are being arranged. Institutes in other branches of medicine and surgery, such as dermatology, orthopaedic surgery, genito-urinary diseases, diseases of the chest, and cardio-vascular diseases, may be included later as staff, equipment, and accommodation of a standard approved by the University can be provided, and their facilities for research and teaching can be developed; and there is need for extending those already included.

The Central Office of the Federation will be responsible also on behalf of the University for the organization of postgraduate studies for general practitioners in London and the Home Counties, and one of its most important functions will be to advise or provide for the large numbers of graduates from over-seas, from the Dominions, Colonies, and other countries who wish to come to this country for postgraduate work.

An International Centre of Postgraduate Education

For a variety of reasons a majority of the graduates coming to this country from over-seas look to London to provide what they require, but many of them have traditional loyalties to other centres, especially Edinburgh, and other centres in London can provide better facilities in certain special branches such as the treatment of industrial accidents, etc. The Central Office of the British Postgraduate Medical Federation in London should become a channel for distribution to all parts of the country, as well as having a peculiar responsibility for its own area, and a source of information on the postgraduate facilities available in the United Kingdom. Situated in the capital, the main port of entry to the country it would be able to gauge the needs of visitors and, if necessary, initiate arrangements for types of education not already provided or for the extension of provisions where these are inadequate.

Because of its geographical, economic, social, and political position the United Kingdom is suitable for the establishment of a great postgraduate medical organization that would attract and serve graduates from all over the world, and we have special duty to provide such an organization to meet the needs of the peoples and the Universities of the British Dominions and Colonies.

The first aim of this organization must be to provide medical education and training of the highest standard based on University departments staffed and equipped to provide opportunities for advanced study and research. Without this no arrangement, however satisfactory from the point of view of administration or of convenience for the visitors, will succeed, and it will take some years to build up departments on the scale and up to the standards required in all the special branches of medicine and to staff them adequately. In the meantime, much can be done to improve the amenities, to welcome the graduates from over-seas to enable them to spend their time here profitably, and to share our educational opportunities.

Graduates come to this country at various stages in the training and experience and for varying lengths of time. They can be divided roughly into those in need of further education and training and those already established in their chosen careers who come to this country for relatively short periods.

The educational needs of the first group have already been discussed, but in order that they may readily obtain the hospital appointments or places in courses of instruction best suited to their previous training and experience and to the time at their disposal, an extensive information service must be provided and they should be helped to find such essentials as living accommodation conveniently situated to the places where they work. For the second group an efficient service on these lines with help and opportunities to enable them to visit the leaders of the profession in this country and to spend their time here to the best advantage is a pressing need.

As the report of the Interdepartmental Committee on Medical Schools points out, the ideal arrangement in London would be a general hospital and postgraduate medical school with specialist hospitals and institutes grouped around it, constituting a postgraduate medical centre. It should be geographically related to the University, the Royal Colleges, the Royal Society of Medicine, and other cultural bodies. Residential accommodation, dining rooms, reading rooms, library and other common rooms should be closely associated, and the Central Office for the Director of the British Postgraduate Medical Federation where detailed information would be available to visitors should be an integral part of the centre. Even if such a scheme is impracticable now in its entirety, it should be possible in the future, and it should be a duty of the hospital planning authority to be set up under the National Health Service to allocate a site for it as soon as possible. An influential committee is now considering what parts of the centre should be completed first in order that visiting graduates may be adequately received and their requirements met to the fullest extent possible under present conditions. Because of the destruction or closure of many cultural centres abroad the war has created conditions that make it urgent that we in this country should take action now, even though what is practicable should fall short of what is desirable. Every University and medical school in the country should prepare plans and each make its contribution now, for the help of all will be required. As has

already been explained each medical school will have an important part to play under the National Health Service in the postgraduate education of its own graduates and of the medical men in its area, and it will be able to offer a share in its culture, learning, and social life to our guests from over-seas. The first step should be to make these easily accessible to them, for that would be the strongest proof of our welcome and our fellowship with them. If we plan boldly and wisely now the ways and means are more likely to be forthcoming in due course. Medical men can influence the thoughts of individuals, races, and nations, and this country and its Universities have an opportunity to mould the ideals of millions of human beings through the postgraduate medical education they provide.

To obtain the best results it is important that the graduate should be suitably placed in relation to his previous training and attainments and in relation also to the particular career that lies before him. For this purpose visitors from over-seas should be sponsored by a body in the country from which they come and their applications should pass through approved channels. There are already a number of channels, perhaps too many, such as the High Commissioner for India, the Colonial Office, the British Council, and the Nuffield Foundation, each dealing with a special group of graduates, and it may be right that this should be so and that a rigid system would be inadvisable. There is certainly a need for some agreed method of assessment and approval of applicants in their country of origin by medical men and teachers who are aware of the conditions and facilities available in this country, and for a common procedure for placing in this country by a similar

group familiar with the requirements of graduates from over-seas. In this also the Universities should have an important part. The problem for them is not limited to medical graduates, for it includes graduates in all the faculties and also the placing of their own graduates in schools abroad suitable for their further education.

I have endeavoured to show that the National Health Service offers a peculiar opportunity for the successful development and organization of postgraduate education for the medical profession of this country and for ensuring that every medical practitioner, whether engaged in general practice or in one of the specialties, should continue in contact with centres of medical learning throughout his career. If this opportunity is wisely used it may prove to be a decisive factor in making the Health Service a success and a boon to the people of this country. Planned primarily for the medical profession of our own country, such an organization would provide also for graduates from the Dominions, Colonies, and abroad, and our medical schools and hospitals would become a centre of medical study and learning of world-wide importance. I have tried to indicate how a beginning has been made and the lines along which further development might be directed, and that the lead must come from our Universities and Medical Schools. Only they can maintain the requisite standards at this time of expansion and reconstruction, and they will, I hope, be able to raise them. They have the opportunity now, and if they wait till all the desired staff, accommodation, and equipment can be provided they may miss the opportunity. Now is the time to plan, and it is the time also to start boldly.

SOME PRINCIPLES IN THE SELECTION OF MEDICAL STUDENTS

BY

D. H. SMYTH, M.D., M.Sc., Ph.D.

Sub-Dean, Faculty of Medical Sciences, University College, London

The recent report of the Interdepartmental Committee on Medical Schools¹ (the Goodenough Committee) drew attention to some of the problems connected with the selection of medical students. The chief points stressed were the following: (1) selection should not be based wholly on examination results; (2) all candidates should be interviewed, preferably by a small committee; (3) great attention should be given to reports from head masters and head mistresses; (4) the machinery for selection should be supplemented by adequate arrangements for weeding out failures in the early part of the training; (5) there is room for experiment in methods of selection; (6) "the selection of students is such an important duty that it demands and should receive a great deal of time and thought from the authorities of the medical schools both in the planning and working of the arrangements." The first three of these points represent essentially the system which is in common use in most medical schools. The weeding out of unsuitable candidates has not in the past been practised on a very wide scale, and if the process is to be more widely applied a number of problems are raised; these will be discussed later. The suggestions about experiment would appear to be a recognition of the fact that existing methods of selection which worked well in the past may no longer be the best possible in changing conditions, and in fact force of circumstances has already compelled a number of medical schools to experiment in their method of selecting students.

Problems to be Solved

The problems of selecting the most suitable recruits for different occupations has been under serious consideration since the 1914-18 war. The tendency has been to try to replace the older methods of chance, tradition, heredity, social position, and economic pressure by conscious guidance of young people into occupations for which they are most suited. This tendency is seen in the attempt² to separate children at about the age of 11 into schools which can lead to a university course and into those which will encourage cultivation of other talents more useful outside the universities, and in the great development of tests for ability and aptitude for different occupations. Up till 1939 the medical schools had not been greatly affected by these changes, and while the field of recruitment for medical students was gradually widening no undue strain was put on

the machinery for selection. Since about 1939 the problems of the medical schools have been increasing, and it was probably with these facts in mind that the Goodenough Committee spoke of aptitude tests and experiments in selection. Some aspects of the matter have also been discussed by the report of the Committee of the Secondary School Examinations Council appointed by the President of the Board of Education in 1941³ (the Norwood Committee), by the Royal College of Physicians Report on Medical Education,⁴ and from time to time by the medical press; but all these reports have done little more than point out the problems, without discussing ways and means of solving them. The present time, when the future of education in general, of medical education in particular, and of the whole organization of the health services is in a state of transition, would seem to call for a detailed examination of the problem of selection of medical students.

The problem assumes its most concrete form when seen strictly from the standpoint of the selector, and accordingly it is presented from this aspect. The other interested parties are (1) the candidates themselves and their head masters and head mistresses; (2) the medical schools as represented by their governing bodies and by the teachers in the various subjects of the medical curriculum; and (3) not least the community at large, which is going to benefit or suffer from the results of the choice. The selector's duty is to be fair to each of these parties, but it sometimes happens that fairness to one party can be achieved only at the expense of the others. When such a conflict of interests arises the obligations to the medical school and to the community should always be placed before the obligation of fairness to the individual. In general the selector would seem to stand on surest ground if he asks in each case, "Is this candidate the most likely one out of those available to increase the reputation of this medical school, or at least is he or she a person whom we should like to claim as one of our students?" This attitude allows for a desirable individuality in different schools, and will in the long run best serve the general interests.

Applicant/Place Ratio

In the recruitment to any occupation there is a certain ratio between the numbers who wish to enter and the numbers which it is desirable to admit. In each occupation the ratio will

adjust itself to a certain value determined by a large number of complex factors, and will at times vary with changing conditions in the particular occupation or in the community at large. The value of the applicant/place ratio is an index of the task of the selector for each occupation. When the ratio is unity no problem exists; when the ratio has a value less than unity the problem is to attract more applicants; when it is greater than unity the work of selection begins and increases with each rise in the value of the ratio. When it reaches a value of 20 (as it has already done in the case of women applicants in some medical schools) the task of selection becomes a formidable one. In looking for causes of changes in this ratio it can be assumed that among other things the ratio must measure in some degree the popular conception of the conditions of work, the ability required, and the standard of living associated with each occupation. Is there any evidence to suggest the probable direction of change in the applicant/place ratio as regards medicine? This can best be seen by examining separately the two parts of the ratio—the number of places and the number of applicants.

Number of Places

The number of places available in the medical schools can be obtained approximately from the figure for the total annual entry of students, which for the year 1942-3 was 2,250. This figure represents a Government quota based on the average

FIG. 1.—Annual entry of students into medicine, 1914-44.

numbers admitted for the three years 1936-9, and can be taken as the average number of places available just before the war. In the post-war years there are three possible factors which influence the number of places for new entrants into the medical schools: (1) the demand by applicants, (2) the desire of individual medical schools to alter the size of the entry, and (3) a definite national policy to alter the rate of recruitment to the medical profession. Demand for places was in the past a very large factor in determining the size of the entry, and when it increased, as after the last war, schools were willing to increase the numbers admitted. This is evident from Fig. 1, which shows the annual entry for the past 30 years. The demand for places can remain effective in determining the size of the entry only so long as the capacity for expansion of the medical schools has not been reached. As soon as further expansion becomes impossible then increased demand does not lead to an increase in the number of places but only to an increase in the number of applicants rejected. It seems likely that this stage is now being reached, and that numbers of applicants will no longer be a determining factor in the number of available places. The desire to increase or decrease the annual entry is a matter of domestic policy for each individual school. To a certain extent greater numbers mean increased prestige and increased staff and accommodation for research purposes. On the other hand, there is an optimum size for a

medical school. While some medical schools are probably still capable of expansion, some, at least in the opinion of the Goodenough Committee, have already exceeded the optimum size.¹ If the recommendations of the committee are taken as a basis for a rough estimate it would seem that a desire on the part of the medical schools to expand or contract to an optimum size might result in an increase in the number of places available to a total value of 2,500.² A last possible factor is a definite national policy to accelerate medical recruitment. On the whole it seems unlikely that there will be great alteration in the number of available places in the near future, and probably a more important factor in determining the size of the applicant/place ratio will be the number of applicants.

Number of Applicants

For various reasons it is not possible to get definite figures for the numbers who wish to start a medical career. In most medical schools there is no last date fixed for receiving applications, and places are filled up as suitable candidates present themselves. When enough have been selected and a number of reserves chosen no further applications are considered. Hence figures for the total number of applicants rejected after consideration do not give the total numbers who sought admission, and furthermore they will include applicants who sought admission to a number of schools. In spite of lack of figures, there is no doubt that the number of those seeking admission to a medical career is increasing. In the case of women students it is possible to give some figures which show the present trend. At University College in the early 1930's there were about twenty applicants for twelve places. This number gradually rose in the pre-war years, and by 1939 had reached three figures. From 1939 it rose sharply at a rate of about 100 a year till it reached 400, since when it has slowly risen.

It is true that these figures indicate the position in the abnormal period of war, and they are influenced also by the small number of London schools which accepted women, but nevertheless they demonstrate the very sharp rise in the applicant/place ratio. No corresponding figures for men are available, but the number of male applicants for the recent session at University College is about 500, and numbers approaching four figures are rumoured for some provincial medical schools. The important question is whether these figures are greatly swollen by the war and by demobilization, and whether the post-war years are likely to see the demand for places in the medical schools maintained. The analogy of the early 1920's cannot be considered a reliable guide in the present circumstances, as in many ways the situation following this war differs from that following the last; but it may be helpful to consider the points set out below:

(a) *Effects of National Service.*—From 1939 to 1945 training for medicine was a reserved occupation, but the war had two effects on recruitment. Many desirable applicants preferred to serve with the armed Forces, while on the other hand the total number of applicants was swollen by those who sought a career free from interruption by conscription. The future effects of national service are unpredictable till details of Government policy are known as regards its application to university students. Two different views on this subject have been expressed by authoritative bodies. The Norwood report³ favoured the possibility of a six-months break between school and university for a period of national service, while the Committee on Scientific Man-power⁴ thought that science students should be allowed to complete their university courses before undertaking national service. Preferential treatment of any one group—e.g., medical students—will undoubtedly affect recruitment in that group. The problem of demobilization is a more temporary one. It has swollen the number of applicants for 1946, and may cause an even greater problem in 1947.

(b) *Effect of Parental Influence.*—This is probably considerable, and some interesting information on the subject was recently obtained in a survey carried out by the British Institute of Public Opinion.⁵ In this survey the following question was put: "If you had a son starting out in life, what kind of work would you like him to take up?" Those who chose medicine as a career for their children amounted to 7.5% of the total number interrogated. (The number of doctors on the Medical Register is less than 0.2% of the population.) Of those choosing medicine 40% had a son not yet working, and of this 40% nearly half (42%) thought that the son would actually take up medicine. A nearly equal fraction (36%) thought that the son would not eventually take up medicine, and that he would be prevented by the expense of the training. The reliability

such a survey for prediction of the future is open to some doubt, nevertheless the figures do give evidence of the popularity of medicine as a career in the minds of parents. A leading article²¹ the *Lancet* suggested the probable reason. "We must consider popularity of medicine as a career to be greatly influenced by general belief that the material prospects are good."

c) The Ability Needed for a Medical Career.—Evidence on this subject has been obtained by a comparison of the abilities of those who have been selected as medical students with those of the population as a whole in a survey undertaken in Manchester by Younne-White.²¹ The purpose was to determine what fraction of the population outside the universities is capable of benefiting by university education. The method of study was to estimate by means of a "progressive matrix" tests the ability of the students in the different faculties of Manchester University, and to compare the distribution of intelligence with that in the general population. While it is known that between 1.5 and 2% of the population actually receive a university education, the survey showed that 6% of the total population had an ability equal to the average university student, and 24% an ability equal to the university students who could probably complete their courses successfully. In regard to medicine 9.1% of the population had an ability equal to that of the average medical student, while 17% had an ability exceeding the lowest quartile of medical students. Taking the 1931 Census figure of 709,000 for the size of the 18 age group the number of those at the age of university entrance with ability greater than the average medical student would be 63,000, and the number with ability greater than the lowest quartile of medical students would be 120,000. Since the actual number of medical students admitted to the universities is less than 2,500 it is clear there are fairly large untapped resources, at least as regards ability. Considering now the proportion of parents (7.5%) who wish their children to undertake a medical career it would seem that about 50,000 of those of the 18 age group will be under some parental influence to choose medicine, while over 100,000 will have the ability. No doubt many of these will be unsuited on other grounds for a medical career, but the determination of this unsuitability will rest more with the selector than with the applicants or their parents, and the figures suggest that the post-war demand on the medical schools is more likely to increase than to decrease.

Financial Considerations

(d) The Economic Factor.—If inclination and ability to enter the medical profession are of the order just suggested, the numbers of applicants must be restricted by other factors. Burt²² studied the general problem of opportunity for university education by inquiring what proportion of the non-fee-paying school population are capable of profiting by a university education, and what proportion of these fail to get it. Out of 700,000 in the 18 age group about 660,000 belong to the non-fee-paying class, while only 43,000 belong to the fee-paying class. Yet of the former group only 5,000 enter the universities, while of the latter more than 6,000 do. In other words, 0.7% of the non-fee-paying class have a university education, compared with 15% of the fee-paying class. Burt inquired whether these figures could be explained by the fact that average ability is actually higher in the higher income groups. He rejected this idea on the ground that the wide range of ability within each income group, combined with the very large size of the lower income groups, must mean that a big proportion, estimated by him at about 40%, of the children in the non-fee-paying class possessed an ability of university standard, and the barrier which stood between these "mute inglorious Miltons" and a university education was clearly the economic one. The effect of financial hardship was not to reduce the ability of the sufferers but to restrict the achievement which might result from that ability.

Data related more specifically to medicine were obtained by Collier²³ in an investigation into the social origins of entrants to Glasgow University. Undoubtedly conditions in Glasgow cannot be taken as typical of those in the country as a whole. The students are drawn from a very large industrial area, and 36% can be classified as of working-class origin. Glasgow has felt more than most other areas the effects of trade depression. Its entrepreneur class, as Collier points out, contains few "merchant princes." In addition the respect for and the ambition to achieve a higher education are more pronounced features of life in Scotland than in England. (The ratio of numbers of university students to total population is 2.5 times higher in Scotland, and the export of university graduates has long been a feature of Scottish life.) Nevertheless, the figures obtained by Collier are instructive. He divided the entrants to the University into the five social classes based on income level recognized by the Registrar-General. Of all the children born into the top class (the upper and middle professional class) 1 in 70 entered the medical faculty, while of the children born into the lowest social class (the unskilled class) the ratio was 1 in 6,000. During the last few decades there has been an increase in the numbers of those admitted to Glasgow University from the lower social groups, but this wider recruitment has affected much less the

more expensive degrees of medicine and of law than the cheaper M.A. degree. These results of Burt and of Collier give objective evidence on a position which is very generally appreciated, that the economic barrier is one of the most active agents in the selection of medical students.

Under the economic heading one must also consider the effect of the general economic conditions on the entry into medicine. The figures for entry for the past thirty years (Fig. 1) illustrate the inverse relationship between general economic prosperity and entry into medicine. The years of depression in the early 'thirties were accompanied by a rise, while the subsequent economic recovery was associated with a fall. In Glasgow, where entry to the University is probably more closely bound with local prosperity than in some other places, Collier found that the depression in the early 'thirties caused a fall of 7.5% in the total entry to the University. This was, however, entirely due to a fall in entrants for the M.A. degree. The numbers in the other faculties actually rose, and of this rise medicine accounted for 62.5%. This inverse ratio between economic prosperity and entry to medicine is usually attributed to the relative stability of a medical career in times of uncertainty, and there can be little doubt that for the next few years uncertainty about the future will be part of the background of the thoughts and actions of a large section of the population.

There is one further aspect of the economic factor in the selection of medical students. Whatever principles we use for selection, the economic consequences cannot be disregarded, and however long the reckoning the cost must eventually be met. The balance sheet in such a complex process is not one which can be easily visualized, but at least the outlines of it are suggested in two citations by Burt.²⁴ "No extravagance is more prejudicial to the growth of natural wealth than the wasteful negligence which allows genius that happens to be born of lowly parentage to expend itself in lowly work"; and again: "Stupidly organized investments in children's capacities, like other stupidly organized investments, will yield little return; well-organized investments adjusted to the natural abilities of the children affected hold out large promise."

(e) Schemes of Financial Assistance.—If parents' income is of major importance in restricting entry to medicine, then a limiting factor will be the ease with which financial assistance can be obtained. Assistance may come from a number of sources: (i) university scholarships and exhibitions; (ii) leaving scholarships and exhibitions from the schools; (iii) State scholarships; (iv) assistance by local authorities; (v) various funds and trusts catering for particular kinds of needs. It is difficult to obtain accurate figures of students receiving some kind of financial aid. The figure of 25% was arrived at by means of a questionnaire sent out by the British Medical Students' Association.²⁵ The Goodenough report²⁶ gave 11% for an English and 43% for a Scottish university.²⁷ From the point of view of the selector the important questions are: (i) Is the scale of financial assistance likely to increase or decrease? (It is this which will influence the numbers of applicants for medicine.) (ii) Is the award of financial assistance in itself evidence of more than average ability in the recipient—i.e., Is it of any value to the selector to know that an award has already been made? In regard to the first of these questions the Norwood report²⁸ stated: "The aid is inadequate both as regards the total sum available and the sums made available to individuals." The Goodenough report²⁹ was more cautious. In Scotland "the faculty of medicine was drawing students from all classes of the community, and given adequate ability lack of means was not a bar to becoming a medical student." In England and Wales, "while a boy or girl with the necessary aptitude need not be hindered by poverty from entry to a medical school, in fact the medical schools are not recruiting from as wide a field, embracing all sections of the community, as other faculties in the university. . . . There is a strong tendency for parents with small incomes not to give any thought to the profession of medicine as a career for their children." The report³⁰ of the Royal College of Physicians stated boldly: "The field from which medical students are to be selected should be widened by making all university education free, and by the provision of maintenance grants to those students in need." Action on the basis of any or all of these reports is likely to result in financial assistance on a wider scale than at present, and thereby, as we have seen, to increase the problems of the selector.

As regards the ability of the recipients both the Norwood³¹ and Goodenough³² reports criticized the unevenness of the standard required. In some cases it is very high; in others it involves passing Higher School Certificate and being accepted by a medical school. The L.C.C. regulations state: "Candidates who do not satisfy the requirements for an award of a scholarship may apply for a major county exhibition if they have been accepted by a university and have passed the Higher School Certificate or other approved examination." Clearly awards in this class are of no help to the selector, and actually the onus of determining the recipients is put on the selector. But this attitude of local authorities is not illogical. How better could they select the recipients for their awards than by leaving it to those who have experience in selecting for the

profession which the candidate desires to follow? This view was endorsed by the Goodenough Committee: "Provisional acceptance by a medical school should precede the making of an award"; and the report goes on to record the views of other witnesses "that acceptance of a candidate by a medical school should be regarded by the bodies awarding financial assistance as sufficient evidence of ability." Clearly the future developments in provision of financial aid are likely to increase the number of aspiring entrants to medicine, and the general argument developed in this and the preceding sections must point to an increase both in the volume of work of selection and in the responsibility associated with it.

Let us now turn to a consideration of how that work can best be carried out.

Methods of Selection

The basic method of selection in most medical schools is the personal interview, and this is generally agreed to be desirable. Will it be possible in future to interview all applicants, and, if not, what other methods are available to assist the personal interview? Selection by interview is efficient, and indeed physically possible, only when the number of applicants seen can be kept within a certain limit. When that number is greatly in excess of the number of places a preliminary selection can be made by various methods: (1) Closure of entries when enough suitable candidates have been chosen.—This only piles up the number of applicants for the following session. (2) Elimination on strict age limits.—This only postpones younger candidates till the next session. In the case of older applicants it raises some problems, which are dealt with later. (3) Selection on recommendations from head masters and head mistresses.—School testimonials are valuable, but the number who can be eliminated on testimonials is small (the general problem is considered later). (4) Giving preference to certain schools of proved worth.—It is valuable to have contacts with good schools whose head masters help the selector, but the number of schools putting forward good candidates is increasing. (5) Adopting a "zoning" system, in which only applicants from a restricted area are considered.—This happens in some provincial medical schools. The argument probably is that, as the money for the training is raised locally, local candidates should benefit. The grave disadvantage is that it prevents mixing of students from different parts of the country. (6) Holding some kind of preliminary test or examination to assist with the selection—possibly including vocational or aptitude tests.—This is the possibility which offers the most profitable line of experiment and deserves most consideration.

What kind of tests are most likely to pick out the applicants we want?

Qualities and Aptitude

In every discussion of selection of medical students the term "aptitude test" is used. The implication is that objective tests can disclose the possession of qualities specially suited to a medical career. The operative word is "aptitude," and everything depends on how this is interpreted. In the United States aptitude tests have been used for the selection of medical students for some time. The testing was started in 1929, and was soon taken up by the American Association of Medical Colleges, which carried out tests on a wide scale, modifying from year to year. The kind of test used can be seen from the account given by Flack²² of the 1931 tests. These consisted of: (1) scientific vocabulary; (2) visual memory for anatomical drawings; (3) memory for descriptive material; (4) premedical information; (5) learning and retention of material; and (6) understanding of difficult printed material. Flack drew the general conclusion that "aptitude tests have gone a long way towards solving the problems of the medical schools." Just what problems were solved is made clear in the report delivered to the association in 1935, from which it was seen that success was judged by the correlation between the results of the aptitude test and those of the medical examinations. The author was aware, however, that this was not the final criterion of success, as the student who had done best in the examinations did not necessarily make the best general practitioner. He held out no hope of finding a measuring stick which will say, "Here is another Hippocrates, Harvey, Osler, or even Mayo."

It is clear, then, that the word "aptitude" means different things to different people. The "aptitude" tests used by the

American schools were successful in selecting qualities which were not necessarily the ones needed by doctors. The technical meaning of aptitude was not the popular one. As the present discussion is from the medical aspect rather than the psychological one it is perhaps worth while to consider the meaning of aptitude tests, starting from first principles. We can do most logically by inquiring what are the qualities we wish to desire in the final product of our training.

The qualities needed in the various branches of medicine cover a wide range and certainly include the following: intellectual capacity, integrity, ability for hard work, conscientiousness, sympathy, tact, ability to deal with people, organizing ability, manual dexterity, cheerfulness, resourcefulness, ability to make decisions, self-confidence, patience, enthusiasm, interest, staying power, common sense, and many others. In fact there are few useful abilities which can be turned to advantage in some or other branch of medicine. If we consider specific ability in different fields of work, then we must admit that skill or ability in physics, chemistry, zoology, electrical and mechanical engineering, photography, drawing, mathematics, handling and care of animals may find an outlet. So wide is the field of modern medicine that so diverse its problems that scarcely anyone would venture suggest which of all these qualities or which combination of them is most valuable. When one speaks of vocational aptitude tests for medicine it is rather difficult to understand exactly what is meant. The Goodenough Committee's doubtless thinking more of experimental work than of application of any specific tests.

It is known that various tests have been developed in the Services during the war in connexion with selection of personnel for specific tasks, but these are not yet available. Pending further information about such tests it must be confessed that in general the words "vocational" or "special aptitude" applied to tests for selection of medical students are extremely vague if not almost meaningless.

A Simplified Approach to the Problem

At the risk of some over-simplification the large number of qualities which have been listed above as desirable in the medical student might be put into a much smaller number of groups—a process which makes a realistic approach to the problem easier. All the qualities might be arranged into one or other of three classes, which we may call (1) intellectual capacity, (2) character, and (3) interest. (Perhaps manual dexterity could hardly be fitted into one of these groups, but it is of decidedly minor importance and applies to specialized fields within medicine.) Under intellectual capacity is included a number of things: (a) ability to pass examinations; (b) ability to think in abstract terms; (c) ability to form logical inferences from data; (d) ability to record one's experiences and to utilize the recorded experiences of others; (e) ability to subject opinions and ideas to critical examination. In the term "character" we include those virtues, like sympathy, tact, staying power, etc., which all are agreed are among the qualities we desire. By interest we mean something which without ability and character is of limited value, but combined with the other two is likely to be a powerful ingredient in the make-up of the successful student in medicine or any other field. Of these three groups perhaps those qualities classified under intellectual capacity are the most concrete and objective, those coming under character the most nebulous and subjective, while interest is possibly the most difficult on which to obtain any reliable information.

Assessment of Interest

The measurement, or perhaps more correctly the prediction, of interest is extremely difficult if not quite impossible. It is more liable to change than is intellectual ability or character, and it develops only in active contact with a particular occupation. As medical work more than most other occupations differs so much from anything which the candidate has experienced before, an alleged interest must be of limited value, particularly since it must appear to strengthen the applicant's case. On the matter of interest the school testimonial does not always help, as the future interests of the adolescent are sometimes difficult to predict. As the Norwood

eport¹² says: "For some pupils the horizon of occupation is emote." On the whole, attempts to judge applicants by their interest in medicine are not likely to be a reliable or profitable method of selection, and we are left then to make our choice in intellectual capacity and character.

Testing for Intellect and Character

Let us assume that we can apply some sort of test for intellect and character. When we have a small number of applicants it may become necessary to decide which of the two qualities is the more important. To have to make such a choice is always unsatisfactory; the incompetent though well-meaning doctor can be as dangerous as his abler though less honest colleague. In the words of a *British Medical Journal* leader¹³: "It is true that stupid students often make successful doctors, but it is doubtful if they ever make good doctors." This not to advocate ability at the expense of character, but to claim that a combination of the two is necessary. It has been pointed out that a large untapped reservoir of ability exists for the recruitment of medical students. It is just as likely that past methods of selection have left an equally large reservoir of character. The problem tends to offer its own solution by the increasing number of applicants. Provided we can test for character and ability, then each increase in the number of applicants is likely to see an increase in those who will come up to standard in both qualities. Rejection of those who fail in either should give us the candidates we are seeking. When the number is high our standard of both character and ability can be raised accordingly. We want, then, two independent tests or sets of tests—the one for ability, the other for character.

Intellectual ability can be measured by some kind of written examination or test, while character, it is generally felt, can be assessed only by personal contact. With large numbers it is least laborious to subject all applicants to a written test for intellectual ability, and on the results of this a smaller number can be picked out for interview and assessment of character. The problem of selection is now resolved into: (1) What is the best kind of written test for intellectual capacity? (2) What is the best way of conducting an interview for the assessment of character? The two problems are independent. We can experiment with each separately, and a failure in one will still leave us the fruits of the other. If we call neither of these processes aptitude tests we shall avoid the mistake of thinking that our tests are more specific for their purpose than they actually are.

Written Tests of Intellectual Ability

It might seem that the ability of the modern child was as thoroughly assessed as possible by the existing examinations, but actually when candidates seek admission to a medical school there is usually little objective evidence on which to judge ability. The Higher School Certificate Examination might be assumed to be the best standard of assessment, but very few who apply between October and June for admission in the following October have yet sat for this examination. It is usually taken about three months before the time at which entry to the university is sought—i.e., in June for the session commencing in October—and the results are not known until September—i.e., a few weeks before the university session begins. The Ministry of Labour requires candidates to be accepted at a medical school before their eighteenth birthday, and so acceptance, or provisional acceptance, must be given before the Higher School Certificate results are known. Apart from this difficulty, which may be temporary, the different Higher School Certificate examinations vary widely. In addition to those of London, Oxford, Cambridge, Oxford and Cambridge Joint Board, Northern Universities Joint Board, Central Welsh Board, Durham, and Bristol, there are the Intermediate Science Examination and the First M.B., often taken instead. While most candidates for medicine offer physics and chemistry, they differ considerably in the choice of other subjects, the usual being botany, zoology, biology, and mathematics. This diversity of examination and subject makes the Higher School examination unsuitable for comparing the merits of candidates. There are other objections to the Higher School Certificate as a university selection test.

The Norwood Committee¹⁴ questioned the value of examinations based on syllabuses as the best means of selecting entrants to the universities, and particularly of the Higher School Certificate. Another aspect of the problem is the value of the usual written examination as a reliable index of ability (see Hartog and Rhodes¹⁵). All this shows that from the standpoint of the selector the Higher School Certificate is of limited use. It is therefore not surprising that some medical schools are experimenting in examinations for selection of their students, and there may soon be a multiplicity of entrance examinations to the different schools.

There are obvious objections to this development. For the medical schools there is much overlap of effort, and much time and energy of the academic staff is taken away from teaching and research. For the applicant there are still greater disadvantages—only too clearly visible in the case of women now seeking admission to the medical schools. Because of the scarcity of vacancies for women, candidates are advised to apply to several schools, and so have to satisfy the conditions of entry at each. This must lessen the educational benefits of the last years at school—years which should be used to widen the pupil's horizon. School-teachers recognize the problem, and at the 1946 conference of the Assistant Mistresses Association¹⁶ asked that the position of entry of women should be clarified and made more uniform between the different medical schools. An immediate solution to the problem is not obvious. Further experiments in the selection of students are required which must cause a certain amount of difficulty, but it is hoped that teachers and pupils will put up with these temporary setbacks in the interests of a general improvement in the methods of selection.

The difficulties can be lessened by an examination for selection which does not require a fixed syllabus and for which the candidate cannot make special preparation. The only break in school work is the examination itself, and the pupil's education need not be interrupted. This type of examination has already been used by a few medical schools experimenting with selection methods, and it may come to be employed more widely. Such an examination has emerged from a series of experiments during the past five years in the selection of women students at University College, and may be of general interest. Before describing this some possible criticisms may be anticipated. The examination was not an amateurish attempt to disregard the experience of those responsible for the development of the present system of examinations. It is not put forward as the best method for selecting students or even as a good method. Its functions may be better carried out by the suggested reorganization of secondary-school examinations. It represents only an experiment in dealing with a problem which had become too difficult for the existing methods, and details may be of interest to others with a similar problem.

An Experimental Examination

A written test for the selection of women students was first held at University College in the spring of 1942. This examination was a somewhat hurried reaction to a rapid increase in the numbers of applicants, which was making the method of interview unworkable. It proved a great help, and so has been continued with modifications. From 1943 onwards it was advertised in the prospectus and a last day was fixed for receiving applications—originally April 1 but now Jan. 1, which seems to be suitable, and is the date used by some other schools. Most final-year pupils who are contemplating a medical career have made up their minds by that date, and as the results are known before Easter it gives unsuccessful applicants time to change their plans for the following session.

Our earlier attempts to devise an examination depended on interested members of the staff, who thought out questions giving scope for ingenuity, invention, or originality on the part of the candidates, combined with elementary knowledge of physics, chemistry, or biology. For example, we asked:

(a) As a test of ingenuity:—What kind of an experiment would you design to show that saccharin is 500 times as sweet as sugar?

(b) As a test of reasoning:—What is wrong with the reasoning in the following sentence: "The horse obeys man because its eye magnifies man?"

(c) As a test of elementary scientific knowledge:—If you sit down at the dinner-table you notice that (i) your knife feels cold, (ii) the mustard on your tongue feels hot, (iii) the table-cloth is neither hot nor cold. Actually all three are about the same temperature. How do you explain this?

(d) As a test of powers of description:—Describe in detail one of the following operations: (i) making a cup of tea; (ii) filling a fountain-pen; (iii) making a bed.

We also asked arithmetical questions involving the use of logarithms and calculations based on simple chemical or physical problems. There were two groups of candidates in each year—those who wished to enter the first-year course and those who wished to enter the second. At one time we set different papers for the two groups, while at other times we set the same paper. As the examinations were competitive for both groups the differences in standard of first- and second-year candidates did not matter.

Assessment of Results

The answers were marked on a basis of α , β , and γ . Examiners were asked to be economical with α 's and very liberal with γ 's, so that candidates who got several α 's were probably much above the average. From the result of the examination candidates were selected for interview. The examiners had no doubt that the examination was an improvement in selection, or it might be more accurate to say that it seemed to make the selection less a matter of chance, and it certainly reduced the work of interviewing. We did pick out some good students by these examinations, though it must be confessed that some we picked out were not very good. It certainly reduced the number of failures of women students in the Second M.B. examination.

A few years' experience of examinations of this kind showed some weaknesses and difficulties, and also the possibility of improvements. Our amateurish attempts to test general ingenuity provided many questions which looked ingenious, but which were less so when it came to assessing the answers. Or it would be more correct to say that the results could have been assessed with more certainty if the number of scripts had been 40 instead of 400. Certainly the number of candidates severely limits the kind of questions which can be asked. It also means that assistants have to be called in to help with the marking, and then much of the ingenuity of the question loses its point, as the person who thought out the question is always more interested in looking for the subtleties of the answers.

Experience also showed that numerical questions were relatively limited in value. Their greatest virtue is simplicity of marking, but this is apt to be of the "all or none" kind. If a candidate has done well on other questions one hesitates to exclude her on the grounds of a numerical error, while so many candidates get the correct answer that it does not help much with the selection. A similar kind of objection can be made against questions in physics or chemistry put into a numerical form. The ability to write and understand one's own language we considered an important quality, and we tried to assess this by asking for accurate descriptions of things in prose or by means of a précis. The marking of a formal essay was too terrifying. Both these tests—description and précis—proved very difficult to assess. Different examiners felt that they would not like to guarantee a high degree of reliability in their assessments. It must be remembered that we were using as examiners not experts in English but members of the academic staff in the medical faculty. We did this because (a) in an experiment of this kind, where much labour is involved, one has to rely largely on the help of people really interested in the particular problem, and (b) it seemed reasonable not to look for qualities in prospective medical students widely outside the range of those who were to teach them.

Limitations and Drawbacks

The system of marking results as α , β , and γ is widely used, but it has its limitations and drawbacks. It seeks to avoid the appearance of the fictitious accuracy of a percentage, but it is subject to the same causes of variability as the percentage. Particularly in the type of question we are discussing and with

large numbers of scripts there is certain to be a wide variation in the standard of assessment. The latitude in judgment allowed by the α , β , and γ system of marking may sometimes encourage examiners to take less care in trying to arrive at the most accurate assessment possible, and this tendency is increased when the number of scripts to be read is very large. Experience of conducting an examination of this kind makes one consider whether some more objective method of assessment is not available.

There was one other, perhaps more serious, drawback to our examination. The examination should have two functions. It should do the immediate task of picking out the best candidates available at the time; and this our examination did more or less successfully. But it should do something more. It should enable one to accumulate data which can be used in the future. Whether our selection system is good or bad is not something we can know by intuition. We can find out only by recording both the examination assessment and the performance of the students selected. In this way alone can we eliminate what is worthless in our methods and retain what is of value. Actually the kind of questions we used and the system of marking left us with data of little value for future work. Looking back on past results, it was impossible to know or even guess why a particular assessment had been given in any one case and what special feature of the candidate's answer had impressed the examiner. It was also difficult to form an opinion as to the relative value of any particular question for selection purposes. The system did not lend itself easily to progressive experimentation.

In setting out to improve an entrance examination by an experimental method it is important not to underestimate the magnitude of the task. Even if we can record the results and the methods used in assessing there still remains the problem of assessing the product of the selection. At least two or three years must follow after selection before the student reaches the hurdle of the Second M.B. examination, and even then it is difficult to predict how he will do in his clinical studies. Nor is Final M.B. itself the measure of success. The ability to do whatever work is undertaken after qualification is the real ability we should like to test. It is evident that the problem of improving selection by an experimental examination is a long process, and is certainly not one to be solved by any individual or even by any one medical school. Hence the great importance of finding a type of examination to provide more definite data on which the future selector can work.

The "Short Answer" Question

For these various reasons we were led to experiment with a type of question used more extensively in the United States and in this country by those who are interested in the assessment of ability. In the following discussion I propose to call this type of question the "short answer" type in contrast to the "essay" type. The word "essay" is used here not in the sense of the formal essay intended to occupy one to two hours but in the sense that the answer is moulded in essay form—i.e., expressed in the student's own words in properly constructed sentences and arranged more or less into logical paragraphs. The basis of the short-answer question is to substitute for one question of essay type a series of short questions which can each be answered by a few words or sometimes by a single word only. As this type of question has not been used extensively in relation to medical training and examinations it is worth while to consider some of its advantages.

In the ordinary kind of examination there are three factors—the candidate, the examination, and the examiner. For most purposes the candidate is the unknown and we think of him as the only variable. Actually the examination can also be considered as a test either of the particular questions set or, alternatively, of the capacity of the examiners to assess the results. The variability of examiners is known to be at a maximum with just such general questions as we had been using. If we can eliminate one of the three variables—the examiner—we leave only two—the candidate and the examination—and these are the things which we really want to test.

The first advantage of the short-answer question is the elimination of the examiner as a variable, and this is achieved by posing questions to which only one answer is possible, so that discussion of the correctness of the answer cannot arise. The entire elimination of the examiner can be achieved by phrasing the question so that the candidate is offered a number of possible answers out of which the correct one must be chosen. But to retain at the same time the possibility of the candidate's scoring something between 0 and 100% it is necessary to have a large number of questions of graded difficulty, and this also reduces the element of chance in just happening to ask something which the candidate either may or may not know. The second advantage of the short-answer question is to make it possible to deal with very large numbers of candidates without undue labour and without fear of changing standards in assessing results. In fact, the answers can be marked by a reliable clerk. As against this there is the time spent in setting the questions. These need to be carefully constructed so as to yield the best results; but the time spent is at least interesting, and any lapses do not result in injustice to any particular candidate.

When the marks of the short-answer question have been collected it becomes possible to assess the value of the question or selection purposes in a fairly definite way by drawing a frequency curve of their distribution. How this can be used to assess the question will be explained presently, with examples.

One of the purposes of the non-syllabus type of examination is to prevent special coaching, but even dearer to the heart of the "coacher" than the syllabus are copies of old examination papers. Since in the short-answer question the answer is actually written on the question sheet, which must therefore be handed in, the examination paper never becomes public property.

A Preliminary Experiment

In a preliminary experiment along these lines five sets of questions were chosen, which were intended to be a test of (a) elementary science, (b) use of English, (c) capacity to draw inferences from the written word, (d) general knowledge. In the interests of experiment we combined these with essay questions to be answered in the more usual way.* We will deal here only with the short-answer questions, but a statistical analysis of the results of all the questions has been made elsewhere in this issue (p. 367) by J. S. Wilkie. For various reasons it is not desirable to publish the questions in full, but their general form can be seen from a few examples.

1. *Test in Elementary Science.*—Candidates were asked to complete a series of sentences by insertion of a word or a few words in the appropriate space; for example:

Distance is measured in.....
A volt is a unit of.....

The sentences were graded in difficulty. The easiest could be answered by nearly all, the hardest by very few.

2. *Test in Use of English.*—A list of adjectives was given, chosen to include words with a fairly definite derivation, or words with a very precise meaning, or words likely to be confused with others. A series of sentences, each with a blank space, was given, and the candidate was asked to complete each sentence by inserting an appropriate adjective. All the adjectives given did not have to be used. In the following examples the word which ought to have been chosen in each case is given in brackets.

The desire for food is [innate] in the newly born child.
Some animals have [prehensile] tails.

3. *Ability to Form Judgments and Draw Inferences.*—An abstract was given setting out certain arguments, and conclusions based on these. At the end of the abstract a number of statements were made which might or might not agree with what was contained in the abstract. The candidate was asked to say in each case whether the statement was (a) correct or (b) incorrect; or (c) that no evidence was available whether it was correct or incorrect. The judgment of correctness or otherwise was to be based on the information in

the abstract, and not on any other knowledge of the subject which the candidate happened to possess.

4. *General Knowledge.*—Two sets of questions were asked. One was to test general knowledge of a "general" kind. The other was to test general knowledge which might be found specially in people intending to take up a medical career; this was meant to be an approach to the question of interest in medicine.

The Results

The candidates' answers give us certain information about their knowledge of elementary science and of general affairs, and of their ability to use words correctly and to draw inferences. What is the value of these results?

(a) *Elementary Science.*—It is not pretended that the short-answer question gives us a better assessment of the candidate's knowledge of elementary science than does Higher School Certificate. What it does give is a numerical assessment by which different candidates can be compared as regards their knowledge of certain elementary aspects of science, and we hope that this is correlated with their knowledge of other aspects of science. Suppose we had asked a different series of questions, should we have got exactly the same results? Probably not, but the fact that we asked a large number of questions (about 25) graded in difficulty and covering a wide range makes it likely that our assessment will be as reliable as asking a single question demanding a more detailed answer. What we can say with some definiteness is whether the particular set of questions was of a suitable standard of difficulty for our purpose of selection. Fig. 2 is a frequency curve showing the percentage of candidates

FIG. 2.—Distribution of marks for questions on elementary science (senior group).

who obtained various percentages of marks for the questions in elementary science. The curve is obviously skewed towards the higher percentages. If we had set the examination to eliminate a small number of weak applicants the questions would have been very suitable, but as we wanted to select a small number of the best they proved to be badly chosen. The inclusion of a greater number of difficult questions would have resulted in a skewing towards the lower percentages and would have been much better for our purpose. This is the kind of information which is fairly easily obtained in the short-answer question and is of considerable value for the future. A little consideration will show that if an "essay" question had been set of an equal standard the request to examiners to give a small number of a's and a large number of γ's would have been absurd, and if complied with would have given a distribution of marks which did not correspond with the candidates' performance. With the essay form of answer the absurdity would not have been obvious, and examiners who tried to be helpful might still have complied with the request.

(b) *Use of Words.*—Does the numerical assessment we have obtained here represent in any way the candidate's ability to use the English language to express her thoughts? The answer is that we do not know, and we could find out only by correlating the results of our test with some more certain assessment (if this exists) of the ability to use English. It should be made clear that mistakes in the answers did not represent failure to appreciate subtle shades of meaning but were much more in the nature of "howlers," and left no doubt about the lack of knowledge—e.g., "The desire for food is diabolic in the newly born child," or "Some animals have extraneous tails." The numerical assessment obtained we accept as a measure of some kind of ability in the use of words, with the

* For referring to the statistical analysis by Wilkie it should be noted that the questions cited here appeared in the examination in the following order: (1-5) Questions of essay form not discussed here. (6) Elementary science. (7) Use of English. (8) General knowledge with special reference to medicine. (9) General knowledge. (10) Scientific inference.

proviso that if candidates who do well turn out subsequently to be illiterate we reject the test as a bad one.

(c) *Making Inferences.*—Here perhaps we are on safer ground, as the capacity to make inferences probably varies less from one case to another than does the capacity to know the meaning of a certain word or to reproduce a piece of information. In this particular form of question, however, chance plays a part in the result. In each individual section of the question the candidate had three options—"correct," "incorrect," or "no evidence." If she wrote these answers purely at random she had a chance of scoring correctly in one case out of three, so that zero level of assessment is not 0% but 33%. An examination of the frequency curve of the marks

FIG. 3.—Comparison of distribution of marks for first- and second-year candidates in questions on elementary science (A) and inference (B). — — — First year; — Second year.

shows that this is actually the case (Fig. 3) and the curve is fairly symmetrically arranged between 100% and 33%. The element of chance could be reduced by providing a greater selection of answers from which to choose.

It was of some interest to examine the frequency curves for the candidates applying for the first and second year, and to compare these with the curves for first- and second-year candidates obtained in the question on elementary science (Fig. 3). For the inference questions the two curves were roughly the same, whereas for questions on elementary science they were strikingly different, the second-year candidates giving a better performance. This indicated that in the one case—elementary science—we were testing something which depended largely on the extra year's tuition at school, whereas this was not so in the former. Both kinds of qualities—capacity to learn and ability independent of tuition—are of course of interest to us.

The value of the assessment is least certain in the general knowledge question. The argument for using general knowledge as a selection test is that it picks out the person of wide interests and the one who follows current events intelligently. It may also pick out the person with the pigeon-hole kind of mind which can retain names and facts without having any particular capacity to make use of them. It is perhaps best to regard the general knowledge test as very experimental and to keep an open mind on its value. The inclusion of the part of the general knowledge of a more or less medical connexion was an attempt to test for medical interest.

Assessment by Marks

The selection of the successful candidates must be made by some kind of numerical classification of the results. If we have obtained a definite mark for each question, might we have added up and the best candidates chosen by a procedure of arithmetic? Before doing so there are some factors to be considered. In the first place not all the questions are of equal selection value. For example, general knowledge may be more important than ability to make inferences. In making decisions of this kind it is well to remember the arbitrary nature of choice. The modern professional tester of abilities forms his judgments on the relative value of tests much more objectively. He prefers to rely more on a study of the correlation results of different tests than on his feeling as to what is or might not be a test of importance. However, as amateurs we may regard some questions as more or less important than others. Also the meaning of the numerical assessment is always the same. For example, in the question on inference we have already seen that 33% represents the zero mark. The simplest and safest method of assessing the total performance is to arrange the marks of all the questions so that candidates can be divided into quartiles or percentiles. In order to set up a list for interview, candidates in the bottom two quartiles in all questions are eliminated. If this leaves too few, those in the last quartile are eliminated. If it leaves too many, one can begin at the upper end and pick out for interview those who come into the top two quartiles in all questions, or perhaps those who come into the top two quartiles in questions to which we wish to attach more importance. By a continuation of this process a list of any desired size can be made. If one adds to this any candidate who appears in the top quartile of any question, then the chance of overlooking any candidate through a freak bad result in one question is eliminated. The final adjustment of the list will be made in a somewhat arbitrary manner, taking into consideration school testimonials in the borderline cases.

General Conclusions

Our general conclusion with regard to these experiments on short-answer questions was that they were of great value and deserved further trial and experiment, and this is supported by the statistical investigation carried out by Wilkie (see p. 3). The chief advantages were: (1) very great reduction of labour in correcting scripts; (2) greater feeling of confidence that the same standard had been maintained for all candidates; (3) more exact knowledge of the grounds for the numerical assessment in each question, and associated with this more standardization of the selection method, more opportunity of collecting data about the results, and more possibility of seeing how questions could be improved in subsequent examinations. To the psychologist it may seem that we are starting rather naively on a problem which has already been brought to much more advanced stage, and that our experimental efforts to standardize our methods could be short-circuited by the adoption of well-known already carefully standardized tests. It must be remembered, however, that we had to deal with the problem as amateurs, and the presentation of our results is for amateurs like ourselves. If the results of our experiments convince us of the need for professional assistance, then they will not have been in vain. The question of selection by experts is discussed later.

Testing for Character

We have assumed that testing for qualities of character is to be left to interview. All authorities have stressed the importance of character as distinct from ability. Is it possible to adopt any principles for testing character? The case for leaving this as the most important function of the dean of each school has been well stated by Lord Moran, "who the Goodenough Committee" suggested that interviewing was probably best done by a small committee, and that attention should be given to methods developed in the Services. These are made known we must approach this difficult problem independently.

The specific questions we have to answer are the following:
(1) What qualities is the selector looking for in each case?
(2) Can these qualities be quantitatively measured?

rded? (3) How can the results of the selection be ssed? and (4) How can we pick out for the job of ction the people with the greatest aptitude for it?

o tell anyone how to judge character at interview, even if knew, would not be easy. Ability to judge character is of the qualities most people think they possess in high ree, and certainly medical men are no exception. It is cult to know on what each one bases his judgment, as ed it is to know on what one bases one's own judgments. practice all one can say to one's selecting colleague at the of an interview is, "How do you like this candidate?" each person's views, whatever the basis for them, are illy expressed as a like or a dislike. The liking or disliking st then be the thing on which the ability of the selector is be measured. The good selector is he who "likes" candi- es who ultimately turn out to have the traits of character require. The quantitative assessment of like or dislike can roughly recorded in several ways. Each candidate might be into one of a fixed series of classes: e.g., Class 1—a candi- e to be had at all costs; Class 2—a very desirable candidate; ss 3—a good candidate if no better available; . . . Class *n*— t to be taken under any conditions. Another method is to ord each candidate's assessment at interview by a figure for ercentage desirability," based on some arbitrary scale. What se figures mean in relation to the character of the candidate open to some doubt, but what they mean to the selector is rly clear.

In looking for a method of assessing the results of selection e turns to the somewhat analogous problem of assessing the ults of clinical treatment. In comparing different operations e surgeon is not satisfied with an impression that one procedure rather better than the other. He looks for objective evidence the "follow-up." The treated cases are re-examined and air symptoms recorded 6 months, 1 year, 5 years after treat- ent, and a figure is obtained which expresses the value of e treatment in a more or less objective way. Could a similar ethod be applied to the work of the selector? It would mean me officer of the medical school giving a good deal of time collecting periodical reports on the "character" of the idents from members of the teaching staff most in contact h them. One may feel slightly alarmed at the possibility 'this developing into a "Gestapo" system of checking the idents' activities, but this of course is not what we want. tactful dean could find out much of value to record about e students' traits of character without becoming a detective. e process would depend, as even the most objective physical eassessment ultimately depends, on the person entrusted to rry it out.

The selection of medical students has been criticized from any quarters. The British Medical Association in their idence to the Goodenough Committee¹ stated: "The ethods of selection fail to exclude a number who, though ole to pass examinations, have not the necessary aptitude, aracter, or staying power for a medical career." In the orld of sport, when the performance of a representative team ills to satisfy its followers the question is soon asked: "Who lects the selectors?" Let us apply this question to the medical hools.

Selecting the Selectors

The selectors are appointed in different ways in different hools. In some cases the dean or other officer of the aculty makes the selection; in other cases a committee is hosen for the purpose. The dean of the medical school is roably not chosen specially for his selecting abilities, but ore for his general administrative capacity and leadership. he members of the committee are chosen probably as repre- enting various interests within the medical school. Selecting ility may be present in either case, but is probably not very onsciously picked out. It may be that experience is more mportant than innate ability in selecting, but it would seem ossible that there is such a quality as ability to judge character. f there is, then it should be used; if not, much humbug could e saved by recognizing its non-existence. The following ethod might elucidate this point and also help us to find he best selectors.

The candidates, already selected with regard to ability, appear before the dean or the committee. As a result of the interview each

candidate's desirability is expressed and recorded. In the case of selection by committee there may be a joint interview or a series of separate interviews. In either case it is important that an independent assessment should be made by each member of the committee before there is any general discussion of the candidate's merits. Subsequent discussion must lead to the final assessment which will decide the candidate's immediate fate, but for purposes of selecting the selectors we are interested in a permanent record of each independent individual assessment. These individual assessments will be kept and subsequently compared with the results of the 1-year, 2-year, 5-year, or *n*-year follow-up. Initially each person would undertake to serve on the selection committee for a certain term—e.g., 3 years. By this time some results of the follow-up would be available. If it appeared that someone had made more bad guesses than his colleagues he would retire from the selection panel, and be replaced by a new selector. Those who seemed to be more successful would be asked to continue with the work.

If this method seems clumsy, laborious, and uncertain, let us bear in mind that so is the clinical follow-up in many cases. "The object of science," said Galileo,² "is to measure what can be measured and to make measurable what can be made measurable." In the process of investigating ability to select we must consider ourselves at the stage of making measurable rather than of measuring, but then in every new field of work this is the natural order of progress.

Weeding out the Unfit

The view of the Goodenough Committee¹ with regard to weeding out the unfit at an early stage in the training can be interpreted in two ways. It might mean the process as carried out at present, with perhaps a little more strictness in the application. This means essentially weeding out those unable to pass their examinations after a certain number of attempts. In spite of selection the occasional academic failure³ will probably still be found. But weeding out misfits could be applied in another way. We might accept a greater number of medical students than we intend should complete the training, and then at a given stage select an arbitrary percentage of these for further training, or at least select the really successful students, in contrast to the present system of eliminating the obvious failures. The greatest difficulty in this process would be the responsibility of rejecting students on any other than academic grounds. Another great difficulty would be that with the present medical curriculum the rejection, if it were to be at an early stage, would have to be made before the students had started any clinical work—i.e., before it could be seen how they developed in this most important part of their career. In the Services the selector could weed out the misfits at any stage of the training, and they could turn to another occupation with no great feeling of injustice or without waste of time and money in commencing a training which was not to be completed and put to use. But a medical training has little in common with the special short Service courses, and the ruthless weeding out of misfits would raise difficult problems in civilian life. Browning⁴ has suggested wholesale weeding out from a large number of starters as the basis of selection of future medical personnel. It would be of interest to know exactly what the Goodenough Committee had in mind when they spoke of weeding out the unfit. Did they think of weeding out on any other grounds than academic failure, and did they consider the full implications of this?

Some Miscellaneous Factors in Selection

Age

A present tendency is to draw candidates from a rather wide age group. On the youthful side this is because of fear of not being accepted before the eighteenth birthday, and also because of a feeling that the long medical course needs as early a start as possible. Against these fears most medical schools rightly insist that applicants should reach a certain maturity and educational standard before acceptance. The problem of the older applicant is more difficult. We shall omit the case of the Service man, who must receive special consideration. What consideration should be given to the applicant of 25 to 40 whose claims compete with those of the 18's and 19's? The usual story is that the older applicants always wanted to do medicine but could not afford it, and that change in circumstances now makes a medical career possible. If the problem is looked at from the general interest standpoint then it must

we shall see, the difference between the correlations of the two years is not significant.

Taking the average correlations for the two years together, we find:

Questions 1-5, average of the ten correlations: 0.447 ± 0.04
 " 6-10, " " " " " " " " 0.588 ± 0.03

The difference is 0.141, and its standard error is 0.05. It may therefore be taken that the difference is significant.

If we now remove Question 10 from the second part and sum its correlation with those of the first part, we shall obtain a contrast between those questions which might be supposed to depend on intelligence or general scientific ability and those (Questions 6-9) which appear to depend rather on general knowledge or culture. Here the averaged correlations are:

Questions 1-5 and Q. 10, correlated with the totals of the test (12 correlations): 0.4415 ± 0.042 .

Questions 6-9, correlated with the totals of the test (8 correlations): 0.6309 ± 0.031 .

Difference: 0.189 ± 0.05 .

These differences are all in favour of the second part of the test, and this remains true even if we consider the "general knowledge" questions of this second part alone—that is, after the removal of the "intelligence" Question 10. The differences are not very great, but they allow us to say that the general knowledge questions have *at least* as much weight in the totals as have the other questions.

Value of the General Knowledge Questions

So far we have taken the totals as reliable—that is, we have assumed that the test as a whole does select the desirable candidates, and have considered the value of the parts in relation to the whole. Admitting that the test is at least as much one of general knowledge as of intelligence or scientific ability, we still have to attempt an answer to the questions: How far does general knowledge of the kind investigated by the test constitute a desirable part of such a test? How does it correlate with general scientific ability? The questions include no standardized test of intelligence, but we may assume that Question 10 is a test of intelligence and possibly of other qualities desirable in a medical student. For instance, the mode of application of intelligence is one which would be useful in the treatment of scientific problems. It is also possible that some other ability is tested by this question; it might be also a test of self-confidence—but again this is not an undesirable quality in a medical student.

In the absence of any other measure of intelligence let us accept this question as such a measure and see how it correlates with the other parts of the test. As a preliminary study this question was correlated with each of the questions in the first part (Questions 1-5) in the first year. These questions might be expected to correlate highly with a test of general scientific ability, but in no case was there any significant correlation; in some cases the correlation actually obtained was negative. This does not mean that no positive correlation exists, since the numbers are small (118) and the difficulty of marking is great, but we may be sure that there is no *high* correlation between these questions and the one (Question 10) chosen as *intelligence*.

It may here be noted that Question 4 was unusual in that the score of the first year did not differ significantly from that of the second year. This might be accepted as proof that this question is a test of "intelligence" (it also bore signs of exceptionally careful marking); nevertheless it did not correlate significantly with Question 10. It follows, then, either that the absence of a significant difference in averages is not a sufficient proof that a test is one of intelligence, or that the application of intelligence is of various kinds. It is in fact usual in an intelligence test not to rest content with one type of question, but to give a wide range, so that all types of application may be sampled.

Having, in this preliminary trial, failed to find significant correlations, a more extensive investigation seemed to me to be indicated. I now took the figures from the second year, in which the number was greater (258), and, so as to overcome to some extent the unreliability of marking in the first five

questions, I added together the marks for all five questions for each student and made my correlations with the resulting marks.

The results of correlating the totals of Questions 1-5 with Question 10 are given below. For comparison, the results of correlating the totals of Questions 6-9 with Question 10 are also given.

Qs. 1-5/Q. 10..... $r=0.206 \pm 0.060$
 Qs. 6-9/Q. 10..... $r=0.294 \pm 0.057$

It will be seen again that, though the difference between these correlations is not great, it is in favour of the general-knowledge questions. It appears, then, that on the results of this test the questions in general knowledge,* besides their intrinsic value in the selection of medical students, are at least as reliable as tests of intelligence and general ability as the more academic type of question represented by Nos. 1-5.

In comparing the first and second years one question which arises is whether, in any case, one group is more consistent than the other—that is, whether it has a greater or lesser scatter. This can be judged by comparing the standard deviations. In no case was any significant difference found.

Questions Separately Considered

The next part of our study consists in considering each question separately. Here the chief interest centres about the differences in average scores for the two years; in other words, which year did better as a group on each question. As we should expect, on the whole the second year has an advantage over the first, except in those questions which in general form approximate most closely to those of standard intelligence tests. There are, however, two interesting exceptions: In the first two questions the first year did significantly better than the second year.

Without being too litigious I think we may say that this is an additional defect of the first part of the test. It is difficult to imagine what useful quality could be better developed in younger students. Intelligence certainly would not be more fully developed at an earlier age than at a later, and all training and acquisition of knowledge should give the advantage to the older student. However, without further investigation it clearly would not be wise to insist on this point. It is not difficult to think of circumstances which might have had a prejudicial effect on some of the studies of the older group, since both groups received their education during the war, but at different periods.

(Note: In repeating the figures of correlations I have simplified some of them so that they do not agree exactly with those given above. The significance of the figures is of course in no way affected.)

Question 1.—This question involved observation of some easily seen physiological reactions of the human body. The correlations with the total scores were:

First year: $r=0.385 \pm 0.08$
 Second " : $r=0.281 \pm 0.06$

The correlation in the case of the second year was the lowest obtained in correlating the results of the separate questions with the totals.

Average of first year: 53.6
 " " second " : 50.0

The first year did better on this test, the difference being 3.6 and the standard error of the difference 1.3. Hence the difference is significant. I do not know why this should be so.

Question 2.—A question concerning methods of teaching two school subjects. The correlations with the total scores were:

First year: $r=0.482 \pm 0.07$
 Second " : $r=0.444 \pm 0.05$
 Average of first year: 50.4
 " " second " : 45.8

The first year did better than the second, the difference being 4.6 ± 1.7 . It may be that the younger group were in a better position to remember the details of teaching of school subjects.

* This does not, of course, apply to any questions in general knowledge, but only to those given in this test. No prediction can be made about a question till it has been tried out.

Question 3.—A question in general biology, not to say agriculture and fisheries. The correlations with the total scores were:

First year: $r=0.436 \pm 0.07$
 Second „ : $r=0.447 \pm 0.50$
 Average of first year: 38.2
 „ „ second „ : 42.4

The second year did significantly better than the first, the difference being 4.24 ± 2.13 . The difference is thus probably, not certainly, significant. The second-year students may have been able to apply their better knowledge of biology.

Question 4.—This was a set of questions more like those of the familiar intelligence tests; it involved the use of the concepts of proximate genus and differentia of species. The relations with the total scores were:

First year: $r=0.616 \pm 0.06$
 Second „ : $r=0.539 \pm 0.04$
 Average of first year: 43.14
 „ „ second „ : 42.64

The difference was 0.50 ± 2.06 ; hence the difference was not significant. This was the only case, except Question 10, in which there was certainly no significant difference between averages. Considering the form of the question, it is probable that it is in fact a test of intelligence, though not of the same mode as Question 10.

Question 5.—This was a straightforward calculation of the length of a chemical solution, given the necessary data. The relations with the total scores were:

First year: $r=0.385 \pm 0.08$
 Second „ : $r=0.400 \pm 0.05$
 Average of first year: 27.7
 „ „ second „ : 36.32

The difference was 8.62 ± 2.54 .

Question 6.—This was set in questionnaire form, involving the use of scientific terms in the appropriate context. The correlations with the total scores were:

First year: $r=0.549 \pm 0.06$
 Second „ : $r=0.451 \pm 0.05$
 Average of first year: 60.8
 „ „ second „ : 75.5

The difference was 14.7 ± 2.04 . Even for the first year the question was too easy, and very much so for the second year. Comparison of this question with the previous one is interesting, because the students knew the terms but could not do the calculations.

Question 7.—This was a questionnaire involving the use of unusual adjectives in appropriate contexts—the context being given, the adjective to be chosen from a given list. The correlations with the total scores were:

First year: $r=0.806 \pm 0.03$
 Second „ : $r=0.680 \pm 0.03$
 Average of first year: 46.7
 „ „ second „ : 53.3

The difference was 11.6 ± 2.2 . The correlation of the first year in this question was the highest obtained. This is not surprising, since vocabulary is known to correlate highly with intelligence, and might also be expected to do so with general knowledge.

Question 8.—This was a questionnaire involving the display of general interest in the history of medicine and in the treatment of medicine in literature. The correlations with the total scores were:

First year: $r=0.701 \pm 0.05$
 Second „ : $r=0.596 \pm 0.04$
 Average of first year: 38.3
 „ „ second „ : 44.4

The difference between the average scores of the two years was 3.6 ± 1.83 .

Question 9.—This was a questionnaire designed to test the general knowledge of the candidates by asking them to specify

for what certain persons of the past and present are famous. The correlations with the total scores were:

First year: $r=0.638 \pm 0.05$
 Second „ : $r=0.624 \pm 0.04$
 Average of first year: 37.54
 „ „ second „ : 41.30

The difference was 3.76 ± 1.93 . Hence the difference is not certainly significant.

Question 10.—This is an elaborate test in deductive reasoning in a scientific context. The answers are given in the form of a questionnaire. Since it was possible to score 30% by chance, the examiners gave 0 for any candidate who did not score more than this. The correlations with the total scores were:

First year: $r=0.327 \pm 0.08$
 Second „ : $r=0.504 \pm 0.05$
 Average of first year: 42.20
 „ „ second „ : 45.35

The difference was 2.95 ± 2.05 . Hence there is here almost certainly no difference between the scores of the two years, and for this reason, as well as because of the form of the question, it has here been accepted as a test of intelligence in the absence of any standardized test. The difference between the correlations of the first and second year is 0.177 with a standard error of 0.09—hence of doubtful significance (see above).

Summary

The test consists of two parts, the first being in the form of questions to be answered by continuous passages of prose—in fact, like any other written examination. The second part is in the form of questionnaires—that is, each question consists of a number of short sentences (subquestions) to which the answer can be given in one word. The purpose of this analysis is to discover whether the first part is in any way superior to the second as a selective test: if it is not, then the practical advantages of the method of the second part are so great that this form would certainly be preferred.

On the given figures, which are for most purposes very reliable, there can be no question of the first part having any advantages over the second. The conclusion, therefore, is that a test set exclusively in the form of questionnaires is as reliable for selection of candidates as one set in the usual form of a written examination.

THE MEDICAL COUNCIL OF INDIA

BY

A. H. BUTT, M.B., D.P.H.
Secretary of the Council

History

The establishment of medical colleges at Calcutta and Madras in 1835 marked the beginning in India of State-organized education in modern medical science. Ten years later the Grant Medical College was opened at Bombay, and in 1860 a medical college was started at Lahore. Although a number of medical schools sprang up to provide training for hospital assistants and sub-assistant surgeons, later known as licentiates, it was not until 1906 that the need for expansion of the teaching for the university standard was recognized. The medical college at Lucknow was established in 1911, an example followed by other centres, and in 1925 there were ten university medical colleges in India, including the Lady Hardinge Medical College, New Delhi, exclusively for women. In the early days the medical colleges granted their own diplomas, but in 1857 the medical college at Calcutta became affiliated to a university and others followed suit.

There was no central or provincial body to register the qualified medical men, to improve their status and standard of education, and to regulate the practice of scientific medicine in the country. Medical education was in the hands of the members of the Indian Medical Service who were qualified in the United Kingdom. In 1892 Part II of the British Medical Act, 1886, which conferred on the General Medical Council the duty

of ascertaining the sufficiency of the examinations leading up to the qualifying examinations, was applied to India, and before 1920 the General Medical Council had accepted for registration the degrees and diplomas of the Universities of Bombay, Calcutta, Lucknow (Allahabad), Madras, and the Panjab. Between 1912 and 1936 all the Provinces in British India, except the North-west Frontier Province and Sind, enacted their Medical Registration Acts in pursuance of which medical councils were established in each Province. These councils, however, were concerned only with the standard of medical education in their respective provinces. There was thus no central or other co-ordinating authority empowered to maintain a minimum uniform standard of medical education for the whole country. Therefore in 1921 the G.M.C. addressed a questionnaire to those Indian universities whose qualifications were recognized by it, and, from the replies received, that Council felt that the teaching of midwifery did not, except in Madras, reach a standard which would be recognized for a university in the United Kingdom.

In 1922, on the invitation of the Secretary of State for India, Sir Norman Walker visited India. In his report he expressed the opinion that each university could bring its regulations sufficiently in accord with the requirements of the G.M.C. to enable that Council to continue to recognize its diplomas. Consequently Colonel Noddham was appointed as Inspector of Medical Teaching in the Indian Universities, and on his reports the G.M.C. continued to recognize the Indian degrees. The Calcutta University did not agree to such inspections by an outside authority, and therefore the G.M.C. withdrew recognition of the qualifications of that university from Nov. 30, 1924. This was, however, resumed on May 13, 1928. The necessity for a central co-ordinating body was more keenly felt after the war of 1914-18, as some colleges were unable to attain the uniform standard required by the G.M.C. and regular inspections by that Council were resented. Early in 1926 a non-official Bill dealing with the subject was introduced in the Council of State, but as it met with opposition in various quarters it was dropped.

Sir Norman Walker again visited India, and in 1928 the question was taken up by the Government of India, and subsequently, in July, 1929, a conference of Provincial representatives was convened. As the conference was opposed to the establishment of such a central authority, the matter was again dropped for the time being. Meanwhile, to meet the criticisms and objections of the G.M.C.—which, since 1922, had recognized the Indian degrees for limited periods only, on the basis of reports submitted by the inspectors appointed on its behalf, and which in 1927 expressed itself in favour of the establishment of an All-India Medical Council with which it could deal direct—the Government of India proposed to appoint a whole-time Commissioner of Medical Qualifications and Standards in India. In view of the opposition the proposal evoked, both inside and outside the Legislative Assembly, it had to be abandoned. The abandonment of this proposal and the non-acceptance by the G.M.C. of an alternative proposal for the appointment, as a temporary measure pending the establishment of an All-India Medical Council, of a board to supervise medical qualifications, led the G.M.C. in February, 1930, to withdraw the recognition of all the Indian medical degrees. A decision of the G.M.C. completely changed the whole sphere and made it imperative to establish a central council. Therefore, in June, 1930, a second conference, consisting of the representatives of Provincial Governments and of all the Indian universities, was convened by the Government of India, and it was resolved that the establishment of an All-India Medical Council was essential and acceptable to it in principle, and that a Bill should be drafted and legislation undertaken to bring the council into existence. Accordingly, a Medical Council Bill was introduced in the Legislative Assembly in September, 1932, and was referred to a Select Committee. The Bill was passed in the Autumn Session of 1933, and the Indian Medical Council Act No. XXVII of 1933 was brought into force with effect from Nov. 1, 1933. In pursuance of this Act, the Medical Council of India came into existence on Feb. 15, 1934.

So much for the history of the formation of the Council. Let us now turn towards its constitution and achievements since its inception.

Constitution and Functions

The constitution of the Council was slightly changed under the Adaptation of India Laws Order, 1937, and now it is composed of: (a) One member from each Governor's Province nominated by the Central Government. (b) One member elected by each British Indian university having a Medical Faculty, to be elected from among the members of the Medical Faculty. (c) One member from each Province where a medical register is maintained, to be elected from among themselves by persons enrolled on the register who possess recognized medical qualifications or medical qualifications granted by a British Indian university. (d) Four members to be nominated by the Central Government.

For the first four years of the Council's constitution the preside was nominated by the Governor-General-in-Council. Maj.-Gen. S. C. A. Sprawson, C.I.E., K.H.P., I.M.S., was nominated as the first president, and he held office till Feb. 13, 1937, save for four and half months when Maj.-Gen. Sir Frank Connor, D.S.O., K.H.P., I.M.S., was nominated in his leave vacancy. After the former's retirement Maj.-Gen. E. W. C. Bradfield, C.I.E., O.B.E., K.H.P., I.M.S., was nominated, and in February, 1938, he was elected by the Council as its first elected president. He was succeeded by Dr. B. C. Roy as the first non-official president, and in October, 1945, Dr. Abraham S. Erulkar was elected to this office.

The secretary was nominated by the Governor-General-in-Council for the first four years from the beginning of the Act. Mr. Farquhar Macrae, M.B., C.M., was the first nominated secretary, and in May 1935, he was succeeded by Lieut.-Col. G. T. Burke, I.M.S. From Nov. 1, 1937, the Council appointed Khan Bahadur Dr. K. A. Rahman, O.B.E., as its secretary. In February, 1946, he was succeeded by Khan Bahadur Dr. A. H. Butt.

The vice-president and the members of the executive committee are elected by the Council from amongst its members. The executive committee consists of seven members, of whom five are elected by the Council, and the president and the vice-president are *ex-officio* members and are also president and vice-president respectively of the executive committee. A member of the Council holds office for a term of five years, and under the regulations framed by the Council the term of office of the vice-president and the members of the executive committee has been fixed for two years.

The medical qualifications recognized under the Act are contained in two Schedules. The First Schedule is composed of medical qualifications granted by medical institutions in British India, and the non-Indian medical qualifications are given in the Second Schedule. Inclusion in the latter Schedule is sufficient qualification for enrolment on any Provincial Medical Register. The Schedules are attached as Appendices I and II.

The functions of the Council fall under two heads: (1) The maintenance of a uniform minimum standard of higher medical qualifications for the whole of British India; and (2) The furtherance of the recognition of these qualifications in States and countries outside British India, with its corollary, the recognition in that country of approved qualifications of such States or countries.

Maintenance of Uniform Standard

Immediately after its constitution the Council drew up its Recommendations on Professional Education and on Professional Examinations. In view of the latest developments and suggestions for, the improvement of the medical curriculum, a revision of the former was undertaken in 1936. The modifications recommended came into operation from 1940. With a view to uniformity in the syllabus of the pre-medical course the Council appointed a board of experts, who formulated the minimum requirements in the basic scientific subjects. Their findings have been forwarded to the Inter-University Board for necessary action. The Council has also laid down minimum qualifications necessary for the appointment of teachers in a medical college.

The first round of inspections of courses of instruction and of examinations of all the British Indian universities was carried out between 1934 and 1938. As a result of this much improvement was effected, and the qualifications of all the universities are now included in the First Schedule. On the recommendation of the Council the M.C.P.S. qualification granted by the College of Physicians and Surgeons, Bombay, has also been placed on the Schedule and is recognized when granted after April 30, 1944. The Council has been engaging itself in inspecting the courses of instruction, and the

ilities for teaching and examinations in the pre-clinical and clinical subjects.

In consequence of the Council's recommendation to the Central Government to ask the Provincial Governments either to abolish the medical schools or to raise them to university standard, the Agra Medical School, Stanley Medical School, Madras, and Amritsar Medical School have been raised to college standard. Steps in this connexion are being taken in other Provinces, and new colleges are being established under the post-war reconstruction schemes. An amending Act, 1942, powers have been vested in the Council to appoint visitors in addition to inspectors.

The Women's Christian Medical College, Ludhiana, and the Lancy Medical College, Amritsar, were visited on behalf of the Council. The Agra Medical College has been inspected, but before deciding the question of the recognition of the M.B., B.S. degree granted by the Agra University, the Council has appointed visitors in order to find out how far the necessary improvements suggested by the inspectors have been carried out.

The Council accorded temporary recognition to certain qualifications—viz., D.M.S. Madras, L.M.S. Panjab State Medical Faculty, S.M.F. Panjab and U.P., M.M.F. Bengal—for purposes of recruitment to the Emergency Cadre of the I.M.S. After a visitation, the M.B., B.S. degree granted by the Osmania and Mysore Universities was also given similar temporary recognition as a war measure. As regards permanent recognition, the Osmania Medical College was inspected on behalf of the Council, and the reports are under consideration. The Mysore University is not yet ready for inspection. Emergency commissions for holders of foreign qualifications not recognized by the Council were disposed of on individual merits by the president.

The executive committee of the Council did not approve of the Government's suggestion that during the war the period of training of medical students should be cut short or the standard of examinations lowered. It was, however, decided that if a member of the staff of a medical college joined the Army, his work might be carried out by the senior students, provided suitable arrangements were made to continue their studies.

In 1937 the Council made recommendations regarding admissions of licentiates to the M.B., B.S. degree. In 1943 certain concessions were allowed, operative during the war and for three years thereafter. These were followed by further concessions, and the periods of training of the different categories of licentiates for the degree have been clarified. The Council has been moving the universities in this connexion, and as an interim measure it requested the Central and Provincial Governments to take steps to provide suitable teaching facilities to the licentiates to obtain the M.B., B.S. degree, by utilizing so far as possible the medical schools and colleges already in existence, and by establishing new institutions wherever possible and necessary.

The Council's proposal for an All-India Medical Register is receiving the consideration of the Central Government. It is intended to include licentiates as well as Indian National holders of foreign qualifications not recognized by the Council but borne on the Provincial registers up to a fixed date. In 1937 the Council made a survey of the teaching in the subject of midwifery, and the information so collected was compiled in a pamphlet. A further survey was made in 1942. The Council has drawn the attention of the universities to the desirability of paying special attention to the teaching of orthopaedics because of its growing importance due to the war. It also suggested that special instruction in the diagnosis and treatment of leprosy on modern lines be provided for students of medical colleges.

Recognition of Qualifications

With a view to making provision relating to medical diplomas granted in the United Kingdom or Burma, which is referred to in subsection (1) of section 120 of the Government of India Act, 1935, the Medical Diplomas Act, 1939, has been enacted by the Indian Legislature.

As a result of negotiations the G.M.C. has accepted for recognition the medical qualifications granted by the British Indian universities included in the First Schedule, except Andhra University. This matter is under the consideration of the G.M.C. It has also been informed of the recognition by the Medical Council of India of the qualification of M.C.P.S. Bombay. In view of the defects pointed out by the inspectors

of the G.M.C. regarding the qualifications granted by some of the Licensing Bodies in the United Kingdom, the Medical Council of India has recommended discontinuance of the recognition of such qualifications; the matter is receiving the attention of the Central Government.

After negotiating with countries and States outside British India, the Council entered into schemes of reciprocity, in some cases direct and in others through the G.M.C., and in 1937 the Second Schedule was revised accordingly. In 1940 the Council did not favour indirect reciprocity, and on its recommendation the Schedule was further amended whereby reciprocity now exists only with Malta, New Zealand, and Burma. The question of mutual recognition of medical degrees between this Council and the South African Medical Council is under consideration by that Council. Medical qualifications granted in Italy and Japan are now recognized only when granted on or before Oct. 10, 1940, and Dec. 8, 1941, respectively.

The Council has asked the Central Government to set up a General Reciprocity Board to facilitate reciprocity between India and the countries comprising the British Commonwealth of Nations, and also to remove, by mutual discussion, any difficulty in the way of establishing reciprocity with these countries, and to maintain it when once established. The matter is being examined by the Central Government and the India Office.

It may be borne in mind that the Medical Council of India has to function both internally and externally within the four corners of the Act under which it has been constituted. It is neither an administrative nor a legislative body. It cannot amend, alter, or change the Act. Even for its finances it has to depend solely on the Central Government. Within its limitations the Council has been doing its best towards the attainment of efficiency at home and honour abroad.

APPENDIX I

FIRST SCHEDULE.—Recognized Medical Qualifications Granted by Medical Institutions in British India and approved by the Medical Council of India

Medical Institution	Recognized Medical Qualification	Abbreviation for Registration
University of Allahabad	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. All.
University of Bombay	Licentiate in Medicine and Surgery	L.M.S. Bom.
	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Bom.
	Doctor of Medicine	M.D. Bom.
	Master of Surgery	M.S. Bom.
University of Calcutta	Licentiate in Medicine and Surgery	L.M.S. Cal.
	Bachelor of Medicine	M.B. Cal.
	Doctor of Medicine	M.D. Cal.
	Master of Surgery	M.S. Cal.
	Master of Obstetrics	M.O. Cal.
University of Lucknow	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Lucknow
	Doctor of Medicine	M.D. Lucknow
	Master of Surgery	M.S. Lucknow
University of Madras	Licentiate in Medicine and Surgery	L.M.S. Mad.
	Bachelor of Medicine and Master of Surgery	M.B., C.M. Mad.
	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Mad.
	Doctor of Medicine	M.D. Mad.
	Master of Surgery	M.S. Mad.
Panjab University	Licentiate in Medicine and Surgery	L.M.S. Pan.
	Bachelor of Medicine	M.B. Pan.
	Doctor of Medicine	M.D. Pan.
	Master of Surgery	M.S. Pan.
	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Pan.
Patna University	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Patna
	Doctor of Medicine	M.D. Patna
	Master of Surgery	M.S. Patna
Andhra University	Bachelor of Medicine and Bachelor of Surgery	M.B., B.S. Andhra
	Doctor of Medicine	M.D. Andhra
	Master of Surgery	M.S. Andhra
	Licentiate in Medicine and Surgery	L.M.S. Andhra
College of Physicians and Surgeons, Bombay	Membership	M.C.P.S. Bom.*

* A recognized medical qualification only when granted after April 30, 1944.

APPENDIX II

SECOND SCHEDULE.—Recognized Medical Qualifications Granted by Medical Institutions outside British India

Country	Qualifications		
UNITED KINGDOM	Registrable qualifications admitting primarily to the <i>Medical Register</i> granted by licensing bodies in the United Kingdom, as shown in Table F set out in the <i>Medical Register</i> .		
Other Countries	Registrable Qualifications		Abbreviations
	Title	Nature of Qualifications as Stated on Diplomas	
AUSTRALIA			
<i>New South Wales</i>			
University of Sydney 	M.B., M.D., Ch.M., B.S.	Medicine and Surgery	U. Sydney
<i>South Australia</i>			
University of Adelaide* 	M.B., B.S., M.D., M.S.	"	U. Adelaide
<i>Victoria</i>			
University of Melbourne†	M.B., M.D., B.S., M.S.	"	U. Melbourne
BURMA			
University of Rangoon	M.B., B.S.	"	U. Rangoon
CANADA			
<i>Alberta</i>			
College of Physicians and Surgeons of the Province of Alberta† ..	Member	"	C.P. and S. Alta.
University of Alberta†	M.D.	"	U. Alberta
<i>Manitoba</i>			
College of Physicians and Surgeons of the Province of Manitoba†	Member	"	C.P. & S. Man.
University of Manitoba†	M.D., M.D., C.M.	"	U. Man.
<i>North-West Territories</i>			
College of Physicians and Surgeons of the Province of North-West Territories†	Member	"	C.P. & S.N.W. Terr.
(When held in conjunction with Licence of the College of Physicians and Surgeons of the Province of Saskatchewan or the Province of Alberta)			
<i>Nova Scotia</i>			
Nova Scotia Provincial Medical Board* 	L.M.S.	"	N. Scotia P.M. Bd.
Dalhousie University* 	M.D., C.M.	"	Dalhousie U.
<i>Prince Edward Island</i>			
Prince Edward Island Medical Council†	L.M.S.	"	M. Co. P.E.I.
CEYLON			
Ceylon Medical College* 	L.M.S.	"	Ceylon M. Coll.
HONG KONG			
University of Hong Kong* 	M.B., B.S., M.D., M.S.	"	U. Hong Kong
ITALY			
All Royal Italian Universities‡ §	M.D.	"	
JAPAN			
All Imperial Universities‡ ¶	M.B. (Igakushi), M.D. (Igaku Hakushi)	"	
Any Government or Prefectural special colleges designated by a Minister of Education of Japan‡ ¶	M.B. (Igakushi)	"	
MALTA			
Royal University of Malta	M.D.	"	U. Malta
NEWFOUNDLAND			
Newfoundland Medical Board†	L.M.S.	"	Nfld. M. Bd.
NEW ZEALAND			
University of New Zealand	M.B., Ch.B., Ch.M., M.D.	"	U.N. Zealand
UNION OF SOUTH AFRICA			
University of South Africa†	M.B., Ch.B.	"	U.S. Africa
University of Cape Town* 	M.B., Ch.B., M.D., Ch.M.	"	U. Cape Town
University of the Witwatersrand, Johannesburg* 	M.B., Ch.B., M.D., Ch.M.	"	U. Witwatersrand
STRAITS SETTLEMENTS AND FEDERATED MALAY STATES			
King Edward VII College of Medicine, Singapore* 	L.M.S.	"	Singapore Med. Coll.

* The qualification must be included in Table I of the *British Medical Register*.

† When granted on or before Oct. 31, 1937.

‡ The qualification must be included in Table J of the *British Medical Register*.

|| When granted on or before March 31, 1942.

§ When granted on or before Oct. 10, 1940.

¶ When granted on or before Dec. 8, 1941.

Medical Memoranda

Post-operative Occurrence of Exophthalmic Goitre

As I have been unable to trace any similar recorded case I feel the following may be of interest.

CASE HISTORY

inese merchant seaman aged 40 was admitted to the Chinese's Home at Birkenhead complaining of a swelling in the oin, with occasional attacks of pain. He stated that the g had always been there but had been lately increasing in The pain had been present for only a month or two.

Examination showed him to be a healthy male. The heart, lungs, and central nervous system appeared to be normal. The pulse was slow, about 64. The right side of the scrotum was empty, and there was a right inguinal hernia. The undescended testicle was indefinitely palpable. The patient was aware of the condition and was anxious to have the testicle placed in the scrotum. When it was explained to him that there was little likelihood of accomplishing this successfully, and even less likelihood of the testicle functioning, he was very distressed, as he was most anxious to return to China and raise a family. By the aid of interpreters it was eventually made clear to him that his remaining sound testicle was quite sufficient. He was greatly relieved at this and cheerfully consented to have his hernia operated upon and, if necessary, his undescended testicle removed.

At operation, under chloroform and ether, it was found that the testicle was only about the size of a thumb-nail and obviously useless. It was therefore removed, and the hernia dealt with in the usual manner. The inguinal canal was completely occluded. The general

condition during the operation was excellent, and the immediate post-operative period passed without incident.

Fourteen days after operation the patient complained of a swelling in the right side of the neck. During the next six days this increased to about the size of a pigeon's egg. At the end of this time a smaller swelling occurred on the left side. On examination it was evident that the swellings were due to enlargement of both lobes of the thyroid gland. Two or three days after the first swelling started it was noticed that the patient's eyes were beginning to "stare." This went on to quite evident exophthalmos. The pulse rate crept up in ten days from his normal of 64 to the region of 85-90. No tremors were present. An obvious diagnosis of exophthalmic goitre was made. No family history of a similar complaint was elicited.

COMMENT

It must be a comparatively rare event for a patient to develop exophthalmic goitre while actually in hospital. The possibility that it was just coincidence is extremely unlikely. It seems improbable that there was any connexion between the fact that an endocrine gland was removed at operation and that a disease involving another gland followed, especially as the testicle was atrophied. The most obvious explanation of the onset is the emotional factors surrounding the operation. One would, however, expect more such cases to occur. The rapid onset of symptoms in the above case brings the apparent cause prominently to the foreground.

I am indebted to Dr. Wilson, the Medical Superintendent, for permission to publish this case.

WILLIAM MCKENZIE KELSO, M.B., Ch.B.,
Surgical Officer, Chinese Seamen's Home, Birkenhead.

Reviews

PRACTICAL ANATOMY

Practical Anatomy. By W. E. Le Gros Clark, D.Sc., F.R.S., F.R.C.S. Professor of Anatomy in the University of Oxford. (Pp. 470; 251 illustrations. 5s. net.) London: Edward Arnold and Co.

Knowledge of the main facts of topographical anatomy is essential for the medical student. Many teachers of anatomy now believe that the student should not be asked to memorize details of topographical anatomy which may be of little value to him in his subsequent clinical studies. While there is general agreement with regard to the main facts which must be taught, there is less unanimity as to what minutiae should be included. By the drastic elimination of superfluous details Prof. Le Gros Clark has succeeded in producing a dissecting manual in one volume. This book is designed to include all aspects of dissecting-room anatomy which will be required by medical students for the 2nd M.B. examination or its equivalent and for their subsequent clinical work. The author makes it clear that the book does not treat of the details of topography which are of importance to the specialist for operative technique. He, like many anatomists, believes that these details should be acquired after qualification. It is only by the elimination of any of the topographical minutiae that time can be found, in an irriculum which is overcrowded, for the teaching of other aspects of anatomy—surface and radiological anatomy, embryology, and post-natal growth—which are of more importance to a student than small points of topographical anatomy.

The book is divided into the following sections: the upper extremity, the lower extremity, the head and neck, the brain, the thorax, and the abdomen. In each section instructions are given concisely and clearly for the exposure and recognition of the main structures, and in addition the dissector is referred to preliminary and supplementary studies before and after the dissection of each region. It is unfortunate that the illustrations do not attain the standard of the text; some of them are too small and diagrammatic to be of much value to the student. In addition the absence of colour in vessels and nerves in some instances makes the illustrations look unduly complicated.

This book will be welcomed by teachers and students alike and will undoubtedly have the success which it deserves in this and subsequent editions.

TEACHING BIOCHEMISTRY

An Introduction to Biochemistry. By William Robert Fearon, Sc.D., M.B. Third edition, revised throughout and enlarged. (Pp. 569. 21s.) London: William Heinemann Medical Books. 1946.

A Textbook of Biochemistry. By Philip H. Mitchell, Ph.D. (Pp. 640; illustrated. 25s.) New York and London: McGraw-Hill Book Company. 1946.

Human Biochemistry. By Israel S. Kleiner, Ph.D. (Pp. 573; 70 text illustrations and 5 colour plates. 30s.) London: Henry Kimpton. 1945.

Of these three textbooks on biochemistry one is now an old friend. It is always a pleasure to handle a new edition of Fearon; first, because this is an indication that the previous edition has probably sold out, which it certainly deserved to do; secondly, because one is confident that the author will have carried out the revision in such a way as to give the student every opportunity of following the advancing fringes of the subject. So, in this welcome third edition, Prof. Fearon now gives full recognition to the importance of Frazer's views on fat absorption; he discusses the uses of tracer isotopes in biochemical research; he uses the logical Levene system for describing the optical rotation and configuration of substances, such as amino-acids, ultimately derivable from tartaric acid, and describes this clearly. On the other hand there seems to be no reference to the fundamentally important work of Tatum and other American geneticists, which lies on a new "borderland of science" and may help to revolutionize our whole method of attacking problems of intermediate metabolism. Some reference might also have been made to the now widely used microbiological methods of assaying amino-acids. The reviewer has noted few statements in this book to which he could take exception on grounds of inaccuracy. But surely the co-enzyme of tyrosine decarboxylase is pyridoxal, not pyridoxyl, phosphate, and must be described in connexion with

the facts now known about the "vitamin B₆ group"? Further, he wonders whether Prof. Fearon could give any literature reference for his explicit statement about the active carotinoids that "transformation of the pro-vitamins into the vitamin takes place in the liver." Possibly, even probably, it does, but where is the experimental evidence to support the possibility? The tendency to over-simplification, of which this is an example, is almost unavoidable in a textbook, unless one is prepared to risk "scattering and confusing" the student. Another instance is to be found in the definition of a vitamin; for man, two of the most important fat-soluble vitamins are not "micro-constituents of the diet," for vitamin D can be made from the pro-vitamin in the skin, the pro-vitamin being almost certainly of endogenous origin (otherwise how do fruitarians get their cholesterol steroids?) and vitamin A is completely "dispensable" from the diet, provided this contains enough of certain carotinoid pigments.

These observations—comments rather than criticisms—serve but to emphasize the outstanding characteristic of Prof. Fearon's admirable book, now a stand-by on the shelves of most British and Irish biochemists. It compels contemplation, comment, even argument. Written with the utmost clarity, simplified to the ultimate possible point and very rarely beyond it, illuminated with flashes of Hibernian wit and with philosophical reflections, implicit as well as explicit, that reveal the traces of that great school of biochemistry from which the author admittedly draws much of his inspiration, showing a willingness not only to consider criticism calmly, but to make use of it in later editions—such are a few of the qualities of what still remains, in spite of competition from overseas, the best general textbook of biochemistry in the English language.

Two of the competitors are also under review. It seems as though no department of an American university were complete without its own professors, associate professors, and other staff members and its own textbook. Otherwise it is difficult to explain the steady stream of new "introductions" to biochemistry that cross the Atlantic. One is by Prof. Philip Mitchell of Brown University and the other by Prof. Israel Kleiner of New York Medical College. Like Prof. Fearon, they have both written with the student first and foremost in mind, but Mitchell's book covers a somewhat wider field at a slightly higher pedagogic level. On the other hand it is devoid of the descriptions of numerous simple practical tests that are a feature of Fearon's book and show that author's contempt for the arbitrary lines drawn by some between work done sitting on benches or standing at the bench. Mitchell's book, on the other hand, wanders far enough from the field generally held to be legitimately the biochemist's as to include a (final) chapter on chemotherapy, which can hardly yet be held to have been systematized into the biochemist's province. This textbook is 12.5% longer than Fearon's (in pages) but nearly twice as heavy in the hand; of such is American book paper.

Kleiner's book is also a useful addition to the large and still growing number of these textbooks. His curious title indicates, according to the author's own explanation, an attempt to link up the medical student's incursions into biochemistry with those problems of human health that will—or should—be his concern. This attitude towards the teaching of students begs certain fundamental pedagogic issues that have frequently been the subject of intense discussion in the columns of this *Journal*. It is not intended here to be drawn into any controversy on the subject. Suffice it to say that Prof. Kleiner's own explanation of his title suggests that it might perhaps more illuminatingly have been called "Humane Biochemistry," to indicate the author's kindly attitude to his student readers. It is perhaps significant that Mitchell's book also includes a preface explaining his attitude towards the writing of textbooks. Fearon, on the other hand, has not reproduced in the present edition his prefaces to the first or second; he gives the baldest of introductory comments and then plunges *in medias res*. There remains to record one curious fact which applies to all three of these books. In each of them there is a specific direction to Rosenberg's *Chemistry and Physiology of the Vitamins* (1942) as a standard work of reference, which it certainly still is. In none of them is there any mention of Prescott and Bicknell's *The Vitamins in Medicine*, which is (in its 1946 edition) naturally more up to date than Rosenberg's book.

A. L. B.

REVIEW OF PHYSIOLOGY

Annual Review of Physiology. Volume VIII. Editor, James Murray Luck; Associate Editor, Victor E. Hall. (Pp. 658. \$5.00 or 30s.) California: Annual Reviews Inc., Stanford University P.O. London: H. K. Lewis and Co. 1946.

This kaleidoscopic presentation of physiological activities appears in its usual form though there are 116 fewer pages than in Volume VII and one review less. In spite of this contraction no one who usually welcomes this work as a means of keeping aware of current advances on many physiological points will be disappointed in the current volume. Since the majority of the reviews cover a one- or two-year period to about the middle of 1945, the contributors have had to deal with a diminishing number of papers, and these published mainly in American journals. Consequently, as a glance at the bibliography attached to any of the reviews will show, the accounts are chiefly of advances in American physiology. It is impossible for a reviewer to read and evaluate critically in the time at his disposal the whole of the 658 pages of concentrated material making up the volume, and only a general impression can be given. The year-by-year reviews on such subjects as "Heart," "Respiration," "Digestive System" each has its particular high lights; thus in the review on the heart there is a timely appreciation of the newer methods of measuring cardiac output. The functions of the cerebral cortex are usefully surveyed in the review on "Somatic Functions of the Central Nervous System," while fresh consideration is given to the so-called antagonism of the sympathetic and parasympathetic divisions of the autonomic system in the allied review "Visceral Functions of the Nervous System." "Applied Physiology" gives an outline of the methods, with their limitations, for assessing physical fitness. It also considers some of the wartime research, now available for publication, on the factors concerned in the acclimatization of the body to extremes of temperature. The same subject is also dealt with to some extent in the review on "Skin," which, however, surveys more fully nutritional factors.

Naturally the reviews are unequal in their standard because this depends on both the author and the material, but it is evident that the editors have persevered with their policy and have endeavoured to choose contributors who would "evaluate with discrimination the present status of the subject" instead of undertaking mere compilation. This seems to be an important attitude to maintain if there is to be any effective synthesis of the great mass of published work in physiology, and in other subjects, and one which might be insisted upon more strongly by the editors of other publications which devote themselves to reviews.

A STUDY OF NORMAL UNDERGRADUATES

What People Are. A Study of Normal Young Men. By Clark W. Heath. (Pp. 141; illustrated. \$2.00 or 11s. 6d.) Massachusetts: Harvard University Press; London: Oxford University Press. 1945.

The old maxim that prevention is better than cure is becoming much more seriously considered in medicine to-day than it ever has been before. But if we as doctors are to keep people normal and healthy we must be much more certain what we mean by normality. Our early physiological training in normal functioning has been too much overlaid by pathology and interest in disease, so that we are apt to think of the normal person as one who does not suffer from illness rather than as one who has certain positive qualities. It was with the purpose of establishing this positive view of normality that the Grant Trust was formed. The present volume describes the findings of investigators under this Trust in a group of apparently normal, healthy, well-adjusted Harvard students. The approach was a wide one: physiological, psychological, anthropological, medical, and social.

It is interesting to note that, in spite of the apparent normality of these young men, 91% had problems which they wished to discuss and in 22% the problems were serious, but the investigators deprecate the assignment of normal people into pathological types such as cyclic, schizoid, paranoid, etc., as they do not think these are valid for the normal. The members of the group were classified according to their general soundness as A, B, or C, and in accordance with their basic characteristics. Some correlation was found between these two classifications, but not always that which was expected. The influence of home

background (economic and social factors, broken homes, etc.) was not nearly so potent in the normal as it was in the abnormal, and the sounder the personality the less did he suffer from conflict. The attitude of this group to such things as delay in physical maturation, divergent interests and capacities, and to frustrations is of great interest. There was a marked variation in morphological characteristics and in physiological reactions, and for this no valid explanation—racial, economic, or other factor—has so far been found.

On medical examination very few of these undergraduates were found to be 100% free from minor blemishes, and a high proportion had been subjected to operative intervention such as tonsillectomy or appendicectomy. It would appear, therefore, that we must not think in terms of an individual example of normality, but rather of a "band" coming within which an individual may be rated as normal, just as in intelligence testing relatively few are found to have an I.Q. of exactly 100% but the vast majority have I.Q.s ranging from 85 to 115%, all of whom can be regarded as normal. Five case histories are interesting, especially in respect of the discussion as to their suitability for university education.

Altogether this is a highly stimulating study, and it is to be hoped that much more work will be done along these lines. Normality is a subject which should be much better understood by members of the medical profession, whether practising in general or in special departments.

Notes on Books

Dr. CHARLES NEWMAN'S *Medical Emergencies* has reached the third edition (J. and A. Churchill; 10s. 6d.). He has been able to condense this admirable book in several ways, particularly by the removal of the section on war gases, as it is to be hoped this will no longer be needed; in any case it would be out of date. On the other hand, the sections dealing with the sulphonamides and penicillin have been added to extensively. The author points out that though there are, of course, many more surgical than medical emergencies, treatment in the latter must frequently be instituted within minutes or even seconds to be of any avail. He defines a medical emergency as being a condition in which accurate diagnosis and prompt treatment are necessary to save either life or great suffering. The various chapters are well compiled, giving the requisite information in a most concise and practical manner. To that end he admits to being dogmatic; at such times it is useless to distract the practitioner's mind between alternative methods. Therefore, in general, he gives only the method which has served him best. A refreshingly practical book.

Introduced with references to *Religio Medici*, and to Oliver Wendell Holmes, *The Physiology of the Newborn Infant*, by Prof. CLEMENT A. SMITH, comes at a time when there has been a great renewal of interest in the care of the baby, especially at this age period. The difficulties in the study of the newly-born are great, which partly explains the comparative neglect of the subject now discussed. But already in this country the work of Barcroft, McCance, and others has indicated what can be done to study the physiology of the foetus and infant. Prof. Smith has gathered together a large amount of work into a series of chapters which are in effect monographs on, for example, respiration, jaundice, the blood, metabolism, and so forth. The nervous system has not been considered, largely because there does not exist any physiological study of this system comparable with what has been attempted in others. Each chapter is carefully documented and a good bibliography for each monograph makes this an excellent work of reference. Not only does the text give a valuable summary of the published work, but anyone specially interested can easily start on a study of original documents. Obstetricians and paediatricians will find this new book a valuable addition to their libraries. It is published in the U.S.A. by Charles C. Thomas of Springfield, Illinois, at \$5.50 post paid.

C. D. DARLINGTON and E. K. JANAKI ANIMAL'S *Chromosome Atlas of Cultivated Plants* (George Allen and Unwin; 12s. 6d.) is an impressive book, for information is provided regarding no fewer than 10,000 species. The word "atlas," incidentally, is applied in its less usual meaning of a conspectus of a subject, and there are no illustrations. It will be of great value to the geneticist, the systematic botanist, and especially to the practical improver of cultivated plants. A brief but admirable introduction shows that the newly acquired knowledge of recent years does indeed provide a bird's-eye view of the whole process of the evolution of genetic systems in flowering plants, and as the authors say: "... already in some sense it shows the plan and proportions of Nature."

SELECTION OF MEDICAL STUDENTS

The interest devoted in the last few years to improving the work of the medical profession has inevitably led to the serious consideration of two questions. What kind of training will equip the future doctor for making the most useful contribution to the health of the community, and how should the best students be obtained? The "Report of the Inter-Departmental Committee on Medical Schools" (the Goodenough Committee) answered these questions with proposals based on comprehensive considerations. On the subject of selection the Committee stressed the need for the authorities and officers of the medical schools to give this subject serious attention. Certain principles in the selection of medical students that are generally agreed were listed, and the suggestion was made that medical schools should carefully consider the extent to which special aptitude tests could be usefully applied. Attention was drawn, in this connexion, to the experience of the services in selecting officers.

That methods of selecting students might be made more scientific has not been ignored. Experiments have been carried out in recent years at various medical schools in the use of certain aptitude tests, chiefly tests of intelligence; but the limited correlation between performance in these tests and examination success has tended to be discouraging. It has also been unfortunate in maintaining the belief that the technician in the field of assessing human assets and liabilities has little to offer of practical value because these tests are the chief "objective" measures he has to hand. Actually, a high correlation between intelligence test scores and examination success would not be expected by the technician, for success is a product of capacity and effort. That is not to say, however, that the estimation of intellectual capacity is unimportant; it merely means that other highly complex factors have to be taken into account. Making an assessment of the potential development of the human being is notoriously difficult. In the physical field there is no one "objective" test for the physical health of the individual. Nevertheless, the physician uses many tests of isolated physical functions in collecting the evidence upon which he bases a judgment. In the psychological field, however, expectations are still widely prevalent that some magical test should be produced that will give "the answer."

The article by Dr. Smyth in this number of the *Journal* is of great value in clarifying many of the issues involved in this complex task of choosing the student. He rightly points out the current confusion associated with the term "aptitude test" in relation to suitability for a career in medicine. "In fact there are few useful abilities which cannot be turned to advantage in some or other branch of medicine." What then is to be sought? If desirable qualities are listed the array begins to create the picture of a somewhat superhuman individual. Smyth wisely notes that the field of medical work is so diverse that few would care to suggest "which of all of these qualities or

which combination of them is most valuable." He then proposes a simplification into three groups in each of which it might be more realistic to attempt an assessment. These are (1) intellectual capacity, (2) character, and (3) interest. Of the last of these he concludes that attempts to judge this are "not likely to be reliable or profitable," because interest can be so much a product of subsequent experience in an occupation. Intellectual capacity, on the other hand, lends itself to relatively objective approaches. The common criteria at present for intellectual capacity are the various certificates or entrance examinations for which the prospective student sits while still at school, and, as Smyth indicates, there are many limitations to the value of these. He describes some experiments with women students made at University College, on the basis of which he found that a short-answer type of question in the fields of elementary science, use of English, capacity to draw inferences from the written word, and general knowledge gave results of great value. Wilkie in his paper (page 367) showed by careful statistical analysis that the assessments made from these short-answer questions were as good as those made from the traditional essay type of question for the purpose of selection. It is therefore possible to get assessments of intellectual capacity by methods much more economical in time and with more consistent standards.

In regard to the judgment of character Smyth assumes the interview to be the most appropriate method of collecting data, and he does not make any suggestions beyond indicating how judges might grade their likes and dislikes. However, he does suggest that judges be assessed in the light of follow-up findings and that those who proved good should be retained, while those who made many mistakes should cease to serve on a selection committee.

The value of Smyth's contribution does not, however, lie principally in his experiments. Indeed, of these he admits that his efforts could be regarded as naïve in view of the vast amount of work by psychologists that has already answered many questions about the technique of examinations. Its value lies rather in the way in which he has considered wider issues than questions of testing procedures. He examines the sources of supply of students and accepts the evidence to show that the resources of the community are not being fully tapped in this respect, largely because of financial barriers. He also points out that the nature of the procedure used will be governed by the applicant/place ratio. In this connexion his survey would indicate that the supply is likely to be much greater than the demand—or rather the capacity to absorb students—for several years to come and that this will be best dealt with by screening procedures. It is here that the psychologist's tests will be likely to be of great value, for they can be used to provide common standards for rejecting all those below a certain standard of ability which is considered desirable if adequate professional competence is to be achieved. Further investigations of the more complex variables such as character and interest can then be devoted to those who pass this first hurdle.

It is gratifying indeed to find that so much careful thought is being given to this serious task. From the standpoint of a modest layman in the field a contribution of importance has been made. What can the expert add? As Smyth remarks, "there is even sometimes a feeling of alarm at the idea that psychologists should take part in selecting medical students." It is probably in this very

issue that the value of the Service experience is most helpful, and it is unfortunate that this experience has not yet been made available. The question put by Smyth, "Should the amateur select when the expert is available?" is not perhaps the right question to ask. Sufficient is known, for example, of the work of the War Office Selection Boards for some of the fundamental questions to be answered in the light of their experience.

The nature of these Boards, the pattern of which was evolved by the technical advisers in the Army, is clearly important, for their wide adoption by the British Army, by several of the Allied Armies, and by the Civil Service for its higher-grade appointments proves that fundamental dilemmas of this kind have been resolved. In these Boards it is a basic principle that the responsibility for the decisions about candidates rests with the President of the Board. He is assisted by regimental officers and by a technical department which includes a psychiatrist and a psychologist. The role of the specialists is two-fold. First, they provide a joint opinion to the President, as do other members, about the candidate. This is based on the results of written tests, observation in various practical situations, and on interview. Secondly, they develop testing techniques for the layman, so that he can make observations and gather evidence in a way that is appropriate to his background of experience in the Service and from which his intuitive judgments derive. Although interesting developments took place in the matter of test methods for assessing "character" and "interest" (particularly with candidates applying for university courses prior to being commissioned in technical arms), the Army experience is just as valuable in the broader questions of planning.

If the selection of medical students is to be advanced in the near future a planned attack must be made on the problem. The overcoming of financial barriers to widen the supply of candidates will mean that entrance to the various schools must be co-ordinated. Common standards must be attempted, otherwise there will be injustice; and the good will and co-operation of the candidates must be secured. This is not to destroy the individuality of the Schools. Each of these will require its own Selection Board, and if the Service experience means anything the Board should comprise a President (the Dean or a Senior member of the Faculty), assisted by other members of the teaching staff and by psychological advisers who include psychiatrists and psychologists. The psychologist has advanced our knowledge of testing abilities, but the major developments in methods for investigating personality have come from medical psychologists. The trend of research in America and other countries in recent years has emphasized the need for medical and non-medical psychologists to work together in teams if their contributions to such practical social problems as selection are to be made as effective as the total range of methods available to the human sciences makes possible.

The task is a complex and urgent one, yet the scientific method is just as applicable as in the somatic field. There is a research problem here of urgent importance. It will include the adequate investigation of methods of getting the best applicants, making a job-analysis from which grounds of selection can be evolved, and working out a procedure which will be satisfactory to the selectors, scientifically adequate to the expert, and manifestly just and helpful to the candidate.

Job-analysis, as the word implies, is an analysis of the work the doctor has to do. In medicine there is perhaps a wider variety of jobs than in any other professional calling. A "doctor" may be an administrator in central or local government, a ship surgeon, a panel practitioner in an industrial city, a medical superintendent, a research worker in physiology or clinical medicine, or a member of the honorary staff of a voluntary hospital. But in all these jobs there are common factors, such as a basic medical training, which provides a minimum of technical competence and draws out a supposed concern for the welfare of fellow human beings. Any method of selection must be based on a full analysis of these common factors. A student selected on this basis, and accepted, has such a wide field of opportunity open to him in medicine that it should not be difficult for him to find a niche that suits him. Analysis of the various jobs available should make the continued process of selection possible. Up to the present the medical student has had to make do with the somewhat haphazard method of self-selection. The role of a selection procedure in relation to training will have to be worked out in practice. To think that selection by itself should produce good doctors is like thinking that the health of the members of an institution would be secured solely by conducting a physical examination on entrance. If the selection procedure is thought of as an initial appraisal its findings can be used throughout training so that the best can be got out of all students. In other words, the more the selection findings can be used for guiding the student and helping him, the easier will it be to achieve both good selection and good training—and enable the qualified doctor to find the job to which he is best fitted.

AN INTERNATIONAL POSTGRADUATE CENTRE

London, with Edinburgh and other academic centres in Great Britain, may yet become the home of a great international postgraduate organization attracting graduates from universities all over the world, and especially from the British Dominions and Colonies. Elsewhere in this issue Sir Francis Fraser, to whom the shaping of the British Postgraduate Medical Federation is mainly due, discusses this possibility. As a pendant to this not immediately realizable prospect is the programme announced by the Nuffield Foundation of fellowships designed to enable medically qualified persons from the British Dominions and India to obtain in the United Kingdom such postgraduate training and experience as may be necessary to prepare them for teaching and research in their own countries. Meanwhile the postgraduate services which London and other centres are building up will be available to those general practitioners who wish to refresh their knowledge, to keep themselves up to date, or perhaps to adopt some form of specialism.

Postgraduate education has laboured hitherto under the disadvantage of being detached from the main stream of medical training. Ideally the education of the medical practitioner should be continuous from the premedical preparation, through the medical curriculum and hospital appointments, to general or special practice accompanied by periodical and seriously pursued postgraduate study. As things are, the postgraduate course fails to sustain the

undergraduate discipline. Undergraduate study has all the advantages of directness, continuity, compulsion, and specific purpose. It leads to examination, qualification, and the practice of a profession. Postgraduate study, on the other hand, is apt to be diffuse, spasmodic, often casually undertaken, uneven in method and uncertain in approach, and, of course, it is optional to the student. The instruction may be systematic and well thought out, or it may be loose and include no definite curriculum or periods of study. It may be inspirational and cultural, in line with the tradition of a university, or it may consist largely of the demonstration of technical procedures. It may mean a vacation course at a clinic, an intensive week-end or two, regular instruction at a selected hospital in general medicine or some approved special subject, or attendance at lectures and discussions arranged by a local medical society. Not that these last are to be disparaged. Osler said that a well-conducted medical society should be a clearing-house in which a doctor could obtain his intellectual rating and estimate his assets and liabilities.

It is because of this lack of uniformity and of authoritative direction that postgraduate education has tended to be unequal in its value and in the quality of its results. This was true in some measure of the Continental schools which during the century between the end of the Napoleonic Wars and 1914 offered postgraduate opportunities to British doctors. Paris was the first of these Meccas, and its principal attractions were the admirable clinical teaching, with at the time no parallel in this country, and the opportunity for studying morbid anatomy. Later in the nineteenth century the wards of the Paris hospitals gave place to the great amphitheatres of Berlin, Munich, and Leipzig, and presently there arose the school of Vienna, which in some respects surpassed all others. Serious study in the famous clinics and laboratories of the Continent was undoubtedly a fruitful and memorable experience in the career of many British doctors. But the quality of the instruction was not always what was claimed for it. It suffered from its very popularity. In a survey of medical education in Europe, undertaken in 1912 for the Carnegie Foundation, Abraham Flexner, brother of the famous pathologist, was very critical of these Continental postgraduate schools. This was at a time when at a number of Continental universities short courses of every description could be arranged. Such courses were indeed the main support of many docents and assistants and constituted the "foreign study" of most of the graduates from Great Britain and other countries. In Vienna the courses ran customarily for five weeks and were held at one or other of the twenty-six different hospitals. Flexner thus describes a clinical course which he attended:

Some of the instructors enjoy an international repute for their skill in hitting off the needs and preferences of the foreign sojourner. Native students are rarely found in their classes. . . . The instructor shows and discusses one case a day: his auditors are seated about the bed, only rarely verifying his pronouncements as to the condition of heart, lungs, tongue, or pupil; none participating actively. In Berlin I observed similar courses in pathology and serology. All the students were foreigners, and the instruction was elementary enough to amuse the docent who, with great skill, vigour, and intelligence, was doing precisely what his little band of transients had paid for.

Thirty years ago, apparently, postgraduate schools in the United States were no better. In a report by the

American Medical Association it is stated that there were no standards of admission to the courses, no definite curriculum, no fixed period of training, and that the granting of certificates and diplomas was greatly abused. Many proclaimed themselves specialists after superficial courses.

London at that time was well in the rear so far as postgraduate teaching was concerned. Some will recall a valiant little effort in what was known as the Polyclinic in Chenies Street, Tottenham Court Road. An organization was also created for the admission of visitors to clinics, lectures, operations, and necropsies at a small number of hospitals, but these were the routine exercises of the undergraduates, and something rather different was wanted for the postgraduate. In Edinburgh and Glasgow vacation courses for graduates were held at the royal infirmaries, the subjects being general medicine and surgery. A tribute should be paid to Scotland, always zealous in education, for much pioneer work in the postgraduate field. Then in 1935 the British Postgraduate Medical School at Hammersmith was opened and has largely canalized postgraduate effort in London. It is out of that school that the new Federation has arisen. Its central office will be responsible for the organization of postgraduate study for general practitioners in the London and Home Counties region and will be a source of information and a channel of distribution for all parts of the country, serving both the home and the overseas postgraduate student.

Many claims could be made for London as the future postgraduate centre of the Empire and beyond. It has twelve great voluntary hospitals associated at present with undergraduate medical schools, thirty other large voluntary hospitals and innumerable smaller ones, special hospitals in every branch of medicine, and the largest and most efficient local authority hospital system in the world. It presents an unrivalled field for observation and study by the visiting student. In addition to the geographical and social advantages of this country the instruction here will be given in a language which is now foremost among all the languages of white peoples. Often in the Continental schools of other days the students were unfamiliar with the language, and so got no real contact with what was valuable or characteristic in Continental medicine.

One promising experiment in postgraduate education which was being tried successfully in London and in other centres before the war was the institution of intensive two weeks' or one week's refresher courses for insurance practitioners. The intention was that every insurance practitioner should attend such a course once in three years and that his expenses, including the cost of a locum tenent, should be met. The Ministry of Health is now contemplating the reintroduction of such courses subject to the willingness of the universities to continue during 1947 the courses of postgraduate instruction they have been providing for demobilized officers. The discussion in the Insurance Acts Committee on the Ministry's proposals will be found reported at page 391 of this issue. All these arrangements are preliminary and without prejudice to those which will be necessary under the National Health Service proposals. The new Service will require an efficient scheme of continuous postgraduate study, and there must needs be such an easing and facilitation of the work of practitioners that they will have time and opportunity to take advantage of it.

issue that the value of the Service experience is most helpful, and it is unfortunate that this experience has not yet been made available. The question put by Smyth, "Should the amateur select when the expert is available?" is not perhaps the right question to ask. Sufficient is known, for example, of the work of the War Office Selection Boards for some of the fundamental questions to be answered in the light of their experience.

The nature of these Boards, the pattern of which was evolved by the technical advisers in the Army, is clearly important, for their wide adoption by the British Army, by several of the Allied Armies, and by the Civil Service for its higher-grade appointments proves that fundamental dilemmas of this kind have been resolved. In these Boards it is a basic principle that the responsibility for the decisions about candidates rests with the President of the Board. He is assisted by regimental officers and by a technical department which includes a psychiatrist and a psychologist. The role of the specialists is two-fold. First, they provide a joint opinion to the President, as do other members, about the candidate. This is based on the results of written tests, observation in various practical situations, and on interview. Secondly, they develop testing techniques for the layman, so that he can make observations and gather evidence in a way that is appropriate to his background of experience in the Service and from which his intuitive judgments derive. Although interesting developments took place in the matter of test methods for assessing "character" and "interest" (particularly with candidates applying for university courses prior to being commissioned in technical arms), the Army experience is just as valuable in the broader questions of planning.

If the selection of medical students is to be advanced in the near future a planned attack must be made on the problem. The overcoming of financial barriers to widen the supply of candidates will mean that entrance to the various schools must be co-ordinated. Common standards must be attempted, otherwise there will be injustice; and the good will and co-operation of the candidates must be secured. This is not to destroy the individuality of the Medical Schools. Each of these will require its own Selection Board, and if the Service experience means anything the Board should comprise a President (the Dean or a Senior member of the Faculty), assisted by other members of the teaching staff and by psychological advisers who include psychiatrists and psychologists. The psychologist has advanced our knowledge of testing abilities, but the major developments in methods for investigating personality have come from medical psychologists. The trend of research in America and other countries in recent years has emphasized the need for medical and non-medical psychologists to work together in teams if their contributions to such practical social problems as selection are to be made as effective as the total range of methods available to the human sciences makes possible.

The task is a complex and urgent one, yet the scientific method is just as applicable as in the somatic field. There is a research problem here of urgent importance. It will include the adequate investigation of methods of getting the best applicants, making a job-analysis from which grounds of selection can be evolved, and working out a procedure which will be satisfactory to the selectors, scientifically adequate to the expert, and manifestly just and helpful to the candidate.

Job-analysis, as the word implies, is an analysis of the work the doctor has to do. In medicine there is perhaps a wider variety of jobs than in any other professional calling. A "doctor" may be an administrator in central or local government, a ship surgeon, a panel practitioner in an industrial city, a medical superintendent, a research worker in physiology or clinical medicine, or a member of the honorary staff of a voluntary hospital. But in all these jobs there are common factors, such as a basic medical training, which provides a minimum of technical competence and draws out a supposed concern for the welfare of fellow human beings. Any method of selection must be based on a full analysis of these common factors. A student selected on this basis, and accepted, has such a wide field of opportunity open to him in medicine that it should not be difficult for him to find a niche that suits him. Analysis of the various jobs available should make the continued process of selection possible. Up to the present the medical student has had to make do with the somewhat haphazard method of self-selection. The role of a selection procedure in relation to training will have to be worked out in practice. To think that selection by itself should produce good doctors is like thinking that the health of the members of an institution would be secured solely by conducting a physical examination on entrance. If the selection procedure is thought of as an initial appraisal its findings can be used throughout training so that the best can be got out of all students. In other words, the more the selection findings can be used for guiding the student and helping him, the easier will it be to achieve both good selection and good training—and enable the qualified doctor to find the job to which he is best fitted.

AN INTERNATIONAL POSTGRADUATE CENTRE

London, with Edinburgh and other academic centres in Great Britain, may yet become the home of a great international postgraduate organization attracting graduates from universities all over the world, and especially from the British Dominions and Colonies. Elsewhere in this issue Sir Francis Fraser, to whom the shaping of the British Postgraduate Medical Federation is mainly due, discusses this possibility. As a pendant to this not immediately realizable prospect is the programme announced by the Nuffield Foundation of fellowships designed to enable medically qualified persons from the British Dominions and India to obtain in the United Kingdom such postgraduate training and experience as may be necessary to prepare them for teaching and research in their own countries. Meanwhile the postgraduate services which London and other centres are building up will be available to those general practitioners who wish to refresh their knowledge, to keep themselves up to date, or perhaps to adopt some form of specialism.

Postgraduate education has laboured hitherto under the disadvantage of being detached from the main stream of medical training. Ideally the education of the medical practitioner should be continuous from the premedical preparation, through the medical curriculum and hospital appointments, to general or special practice accompanied by periodical and seriously pursued postgraduate study. As things are, the postgraduate course fails to sustain the

undergraduate discipline. Undergraduate study has all the advantages of directness, continuity, compulsion, and specific purpose. It leads to examination, qualification, and the practice of a profession. Postgraduate study, on the other hand, is apt to be diffuse, spasmodic, often casually undertaken, uneven in method and uncertain in approach, and, of course, it is optional to the student. The instruction may be systematic and well thought out, or it may be loose and include no definite curriculum or periods of study. It may be inspirational and cultural, in line with the tradition of a university, or it may consist largely of the demonstration of technical procedures. It may mean a vacation course at a clinic, an intensive week-end or two, regular instruction at a selected hospital in general medicine or some approved special subject, or attendance at lectures and discussions arranged by a local medical society. Not that these last are to be disparaged. Osler said that a well-conducted medical society should be a clearing-house in which a doctor could obtain his intellectual rating and estimate his assets and liabilities.

It is because of this lack of uniformity and of authoritative direction that postgraduate education has tended to be unequal in its value and in the quality of its results. This was true in some measure of the Continental schools which during the century between the end of the Napoleonic Wars and 1914 offered postgraduate opportunities to British doctors. Paris was the first of these Meccas, and its principal attractions were the admirable clinical teaching, with at the time no parallel in this country, and the opportunity for studying morbid anatomy. Later in the nineteenth century the wards of the Paris hospitals gave place to the great amphitheatres of Berlin, Munich, and Leipzig, and presently there arose the school of Vienna, which in some respects surpassed all others. Serious study in the famous clinics and laboratories of the Continent was undoubtedly a fruitful and memorable experience in the career of many British doctors. But the quality of the instruction was not always what was claimed for it. It suffered from its very popularity. In a survey of medical education in Europe, undertaken in 1912 for the Carnegie Foundation, Abraham Flexner, brother of the famous pathologist, was very critical of these Continental postgraduate schools. This was at a time when at a number of Continental universities short courses of every description could be arranged. Such courses were indeed the main support of many docents and assistants and constituted the "foreign study" of most of the graduates from Great Britain and other countries. In Vienna the courses ran customarily for five weeks and were held at one or other of the twenty-six different hospitals. Flexner thus describes a clinical course which he attended:

Some of the instructors enjoy an international repute for their skill in hitting off the needs and preferences of the foreign sojourner. Native students are rarely found in their classes. . . . The instructor shows and discusses one case a day: his auditors are seated about the bed, only rarely verifying his pronouncements as to the condition of heart, lungs, tongue, or pupil; none participating actively. In Berlin I observed similar courses in pathology and serology. All the students were foreigners, and the instruction was elementary enough to amuse the docent who, with great skill, vigour, and intelligence, was doing precisely what his little band of transients had paid for.

Thirty years ago, apparently, postgraduate schools in the United States were no better. In a report by the

American Medical Association it is stated that there were no standards of admission to the courses; no definite curriculum, no fixed period of training, and that the granting of certificates and diplomas was greatly abused. Many proclaimed themselves specialists after superficial courses.

London at that time was well in the rear so far as postgraduate teaching was concerned. Some will recall a valiant little effort in what was known as the Polyclinic in Chenies Street, Tottenham Court Road. An organization was also created for the admission of visitors to clinics, lectures, operations, and necropsies at a small number of hospitals, but these were the routine exercises of the undergraduates, and something rather different was wanted for the postgraduate. In Edinburgh and Glasgow vacation courses for graduates were held at the royal infirmaries, the subjects being general medicine and surgery. A tribute should be paid to Scotland, always zealous in education, for much pioneer work in the postgraduate field. Then in 1935 the British Postgraduate Medical School at Hammersmith was opened and has largely canalized postgraduate effort in London. It is out of that school that the new Federation has arisen. Its central office will be responsible for the organization of postgraduate study for general practitioners in the London and Home Counties region and will be a source of information and a channel of distribution for all parts of the country, serving both the home and the overseas postgraduate student.

Many claims could be made for London as the future postgraduate centre of the Empire and beyond. It has twelve great voluntary hospitals associated at present with undergraduate medical schools, thirty other large voluntary hospitals and innumerable smaller ones, special hospitals in every branch of medicine, and the largest and most efficient local authority hospital system in the world. It presents an unrivalled field for observation and study by the visiting student. In addition to the geographical and social advantages of this country the instruction here will be given in a language which is now foremost among all the languages of white peoples. Often in the Continental schools of other days the students were unfamiliar with the language, and so got no real contact with what was valuable or characteristic in Continental medicine.

One promising experiment in postgraduate education which was being tried successfully in London and in other centres before the war was the institution of intensive two weeks' or one week's refresher courses for insurance practitioners. The intention was that every insurance practitioner should attend such a course once in three years and that his expenses, including the cost of a locum tenent, should be met. The Ministry of Health is now contemplating the reintroduction of such courses subject to the willingness of the universities to continue during 1947 the courses of postgraduate instruction they have been providing for demobilized officers. The discussion in the Insurance Acts Committee on the Ministry's proposals will be found reported at page 391 of this issue. All these arrangements are preliminary and without prejudice to those which will be necessary under the National Health Service proposals. The new Service will require an efficient scheme of continuous postgraduate study, and there must needs be such an easing and facilitation of the work of practitioners that they will have time and opportunity to take advantage of it.

UNESCO AND MEDICAL CONGRESSES

A little less than a year ago an international conference was held in London to draft the constitution of the United Nations Educational, Scientific, and Cultural Organization—UNESCO—as a specialist agency of the Economic and Social Council of UNO. The headquarters of UNESCO will be in Paris, and a general conference of the new organization will be convened there in November of this year. The following statement defines the general objective of UNESCO: "The States parties to this Constitution, believing in full and equal opportunities for education for all, in the unrestricted pursuit of objective truth, and in the free exchange of ideas and knowledge, are agreed and determined to develop and to increase the means of communication between their peoples and to employ these means for the purposes of mutual understanding and a truer and more perfect knowledge of each other's lives." Among the functions of UNESCO are the maintenance, increase, and diffusion of knowledge by, among other measures, "initiating methods of international co-operation calculated to give the people of all countries access to the printed and published materials produced by any of them."

The work of UNESCO is to be done through various divisions, and medicine will find its place in the Natural Sciences Division, at the head of which is Dr. Joseph Needham, F.R.S., assisted by Dr. I. M. Shukova and others. Medicine offers a fruitful field for co-operation among the various countries of the world. The problems of medical science are international, and in these days no doctor in one country can afford to be ignorant of what doctors in other countries are doing—this quite apart from the question of the spread of infection across national frontiers now facilitated by air travel. Before the war some attempt was made to diffuse medical knowledge through the holding of international medical congresses in various special subjects. It is, however, not unfair to say that the arrangements for these congresses were fitful and depended often enough upon the enthusiasm of individuals. Not only was there some lack of continuity in the congresses arranged for a special subject, but there was no co-ordination between the various congresses in respect to either time or place of meeting. It would, for example, be a great convenience if congresses in related subjects could be held at the same place in a given year with an interval, say, of two or three days between each. A gynaecologist attending an international congress of obstetrics and gynaecology would find it a great convenience to pass straight on to, say, an international congress on endocrinology if he knew well in advance that these two congresses were to be held in Paris in a certain year, with an interval of one or two days between each. On occasion two congresses might overlap in time with a view to giving up one or two days to joint discussions. There is no need to labour the point further, but if in fact some central co-ordinating mechanism could be devised much time, effort, and money could be saved, and the world of medicine would benefit greatly.

The Natural Sciences Division of UNESCO under Dr. Needham is now considering what steps could be taken to achieve this desirable end. The moment could not be more opportune, because various international organizations are now trying to pick up the threads of their peacetime work and are revising their constitutions and planning future congresses—but all this in ignorance

of what other similar organizations are up to. The Natural Sciences Division of UNESCO hopes that it may be possible some time next year to hold a conference in Paris of delegates of the various international medical congresses and societies with a view to forming some small central organization within UNESCO which will help the various congresses in their numerous problems and so co-ordinate meetings to the greatest convenience of those taking part in them. What might emerge from such a conference would be a Permanent Commission of International Medical Congresses with a small secretariat linked to the Natural Sciences Division of UNESCO. In this way congresses could be arranged so that there would be no confusion of time and place in the various meetings and so that meetings of congresses in related branches of knowledge could be correlated. With the funds that will be at their disposal UNESCO could obviate some of the financial obstacles to travel in the case of those in need of assistance as well as facilitate the transit of delegates from different parts of the world. Through its field science co-operation stations in different countries UNESCO would also be able to secure the co-operation of various national organizations. To diffuse as widely as possible the information that would be forthcoming in the various conferences the proceedings of the various meetings could be published in full in an international journal at whatever frequency experience might show desirable. A monthly bulletin could also be issued which would give details of future meetings, of arrangements for travel, and of the help that UNESCO would be able to extend to various national delegates. This work, too, would presumably be linked with that of the World Health Organization.

These plans are yet in the formative stage and can come out of this stage only if the full and willing co-operation of those now responsible for the work of the various international congresses is secured. It is much to be hoped that co-operation will not be withheld. In a world still sadly out of tune because of national discords the world of medicine has here a chance to show how professional groups, through unity of interest, can give a useful object lesson to the politicians whose rantings so often tend to smother the small voice of reason. We would urge those interested in the plan outlined above to communicate with Dr. Joseph Needham, F.R.S., at the Headquarters address of UNESCO, Natural Sciences Division, 19, Avenue Kléber, Paris, XVI^e.

MEDICAL STUDENTS IN WARTIME

The teaching hospitals unfortunately suffered badly from aerial bombardment during the war: buildings and great quantities of equipment were destroyed often overnight, travelling facilities disrupted, and the time of students and teachers sometimes occupied by dealing with emergencies rather than by an orderly educational programme. The London schools suffered most severely, and the circumstances prevailing in the latter half of 1940 enforced their rapid dispersal throughout the sectors of outer London. This physical displacement, combined with the anxieties aroused by our critical situation in the early years of the war and by the blitzes, laid a heavy burden on students already encumbered with the longest of all academic curricula. That these trials were overcome as successfully as they were—an achievement that will be appreciated

especially by those who had any experience of the ineptitude of the young medical officers in the German Army—is due as much to the untiring devotion of depleted and overworked teaching staffs as to the sense of duty displayed by the students themselves. Medical students were of course reserved from military service; the production of doctors was as important as that of bombers; and the duty laid upon teachers and students alike of producing a sufficiency of suitably qualified men was accepted with praiseworthy vigour.

Education as judged by examinations was maintained at a sufficiently high standard; but what of those less easily measurable qualities that exist in all corporate educational institutions—the relationships between students and teachers, the fellowship among the students themselves? To a certain extent the breaking up of the schools was compensated by that sense of national solidarity that pervaded the whole country during the war. Pride at being a member of an honoured and ancient institution naturally declined, but the feeling of being a valuable member of the community as a whole replaced it; the student found in his class something of the comradeship originating in a common and compelling purpose that the soldier derived from his unit. In many cases closer relations between students and teachers were established than had been customary in peacetime; the smaller groups and the difficulties under which they lived (not the least of which was the shortage of textbooks) favoured the growth of oral discussion. A greater variety of clinical cases was often available for teaching purposes; and ingenious expedients and improvisations performed by doctors in general practice, and normally obscured by the perfect organization, plenitude of supplies, and suitable accommodation of teaching hospitals in peacetime, were brought to the notice of the student and incorporated almost unconsciously into his knowledge of medical practice.

Perhaps in the long run the defect in wartime education most to be regretted will be that arising from the lack of any leisure. The student's life was immersed in the acquisition of medical knowledge and the overcoming of obstacles to that end; there was little time for the pursuit of those cultural interests that make a man something more than an efficient technician. This tendency has been apparent in the medical profession for the last twenty-five years; the recent war has done much to accelerate it. It should be the duty of teachers in the immediate future to stress the importance of the epithet "learned" when speaking of our profession. *Gray's Anatomy* conveys no philosophy of life except perhaps the discipline of minute observation; and however necessary this may be to the medical student he will find that his patients will expect him to be not only acquainted with the innervation of the tongue but also able to put that organ to such good use that he may be regarded as a man of uncommon wisdom.

THE MEDICAL WOMAN GRADUATE

The quotas of admission at the various medical schools appear to show that about 500 places are available to women students. This is about one-fifth of the total admissions for the year. The figure given in the Goodenough report for the academic year 1942-3 was 470, or about 21% of the total. The Goodenough Committee came down strongly on the side of co-education, holding that this should be the normal practice in every medical school, and even recommended that Exchequer grants should be conditional upon the schools' admitting a reasonable number of women students. By a "reasonable number" it explained that it meant about one-fifth, though exactly

on what basis that proportion is decided is not clear. At one of the schools (Leeds) from which we received information about the new session it was stated that during the war the proportion of women students to men had risen steadily until it reached rather more than one to three, and in spite of this increase approximately thirty applications were received last year for each place that could be allocated to a woman, while for the coming session the number of applications was still larger. If that is the general experience of medical schools the number of young women desiring to enter the profession must be much greater than is commonly supposed. With the opening of more school doors to women there will be less frustration than has been experienced in the past.

In 1944 the Senate of the University of London set up a committee under the chairmanship of Sir Henry Dale to report on the provision of facilities for the medical education of women in London, and, like the Goodenough Committee, this body also urged the opening of all medical schools to women on terms of equal opportunity. The principle of co-education, if it were carried out in London, would have the curious result of admitting men to the London School of Medicine for Women. This school was established to overcome the difficulty which women had in obtaining admission to the medical profession, and it has done excellent pioneering work. It has stated that in the interests of equality it is prepared to make the innovation whereby men as well as women students would be admitted. Another school which during the war years accepted women students only is the West London Hospital Medical School. It is not a pre-clinical school, but its acceptance of about thirty clinical students annually has been of considerable service. Glasgow is a university in which, not in the faculty of medicine alone, women students have always been found in large numbers. In the medical school they are admitted on equal terms with men, and it is stated that owing to the relatively larger number of women applicants the educational standard of the women admitted is conspicuously high. Everywhere the tendency seems to be towards co-education, and one day sex discrimination will be as extinct in medical education as it is in other education and professional fields. But if women are to be admitted they should be ungrudgingly admitted. There is nothing at all to be said for a policy of opening the door to admit a stated minimum and making them feel that they are unwelcome. If the thing is to be done it should be done graciously and gallantly. It is important also that not only should women be admitted to the schools, but that they should have a fair chance of appointments afterwards. The British Medical Association for the last forty years has done much to champion the cause of equality between the sexes with regard to medical appointments and to the emoluments attaching to them. It was not always so even in the history of the Association. It is true that in 1873 Elizabeth Garrett Anderson, who had qualified L.S.A. eight years previously, and had afterwards obtained the diploma of Doctor of Medicine of the University of Paris, was elected by the Metropolitan Counties Branch as a member of the Association. She was not, by the way, the first Englishwoman to obtain a medical degree. The first was Elizabeth Blackwell, who graduated M.D. at the University of Geneva, New York State, in 1849, but was unable to get her name in the first *Medical Register* of 1858. But after Elizabeth Garrett Anderson's election there arose a considerable controversy on this subject, and a plebiscite taken in 1878 showed a majority of three to one against the eligibility of women for membership of the Association. The restriction was broken down in 1892, and since then women have been elected on a perfect equality with men.

EXAMINATIONS

MEDITATIONS ON A PAINFUL THEME

BY

FF. ROBERTS, M.D.

The important part which examinations are destined to play in our lives is impressed upon us at an early stage in our tutelage. On our arrival home for the holidays we were invariably greeted by our elders with the rather impolite question, "When do you go back?" This we could bear, but worse followed: "Have you passed your School Certificate?" (or "your Higher," or whatever it might be). These unsolicited reminders of our shackles were, it is true, intended as compliments, for it was assumed that a positive answer would be forthcoming; if we happened to have failed there followed a profusion of embarrassed condolences. Of these tactless attentions medical students receive more than their fair share by reason of the long series of examinations which fall to their lot.

Considering their formidable nature, examinations have a remarkable capacity for acquiring pet names—Little-go, Mods, Inter, Stinks Trip, and (formerly at Cambridge) Bugs and Drugs. But such euphemism is not surprising; it is only one example of man's age-long habit of trying to placate evil spirits by pretending to credit them with virtues which they are far from possessing. We give the most painful diseases the loveliest names; the Greeks called the Furies the Eumenides, and sought to make the Black Sea less stormy by changing its name from "Αἰετος to Εὐχαιρος."

Rather naturally, examinations are a favourite subject for oratory at prize-givings and at openings of new sessions. Here examiners are wont to be exhibited, frolicsome as elephants at a circus and human as film stars at a theatrical garden-party, and there is no doubt that students thoroughly enjoy these back-stage revelations, secure in the knowledge that the tiger (to change the metaphor) is safely behind the bars of the ceremonial occasion. After relating a few "howlers" from their unlimited repertoire the distinguished speakers deliver themselves of the old clichés, such as, "Examinations are good servants but bad masters." They then proceed to condemn examiners who "try to find out what you don't know," thereby leaving it to be inferred that they themselves are not of that category. In descending to such banality they ignore the fact that discovering what a candidate knows and discovering what he does not know are essential parts of the same process. His knowledge stands against a background of ignorance. An examiner would rarely have any difficulty in finding out a candidate's deficiencies if such were his intention. He is, however, at any rate in written examinations, bound to a rigid code and to a standard controlled by his colleagues, by the Examining body which employs him, and by the traditions of the examination. Moreover (candidates may believe it or not), most examiners in correcting papers are obsessed with the fear of being unjust and will go to more pains than candidates deserve in deciphering bad handwriting and in striving to comprehend confused expressions, though they may in the process become prejudiced against the scribblers. Candidates, on the other hand, have far more ethical freedom. They have merely to "satisfy the examiners" in the literal meaning of the term, and they may employ window-dressing as freely as their cunning can suggest. If their bluff comes off the more fool the examiner. An undergraduate may steal a policeman's helmet if he can get away with it, but the policeman may not steal the undergraduate's cap.

The Nature and Purpose of Medical Examinations

At the period of life when Nature imposes the strain of physical growth modern civilization finds it necessary to add a mental strain the like of which is rarely experienced after maturity is reached; and strangely enough we display more intelligence in assessing Nature's handiwork than we do in assessing our own. We judge the rate of physical growth by height and weight, and by races, games, and other feats of endurance, taking care that these trials do not cause over-strain and that we test no more than the maximum capacity obtaining at the time. What we test is ultimately the effect of the assimilation of food and environment on the growing body. The

scientific education given to medical students, however, is concerned neither with assimilation nor even with complete digestion, but rather with partial digestion, and the examinations are nothing more than test-meals of the crudest kind. After a period of forcible feeding vomiting is induced and samples are laboriously analysed. Conditions are as unphysiological as they can possibly be, for what is being tested is not a normal end-product but an abnormal intermediate stage. Nor is any trouble taken to make the pabulum assimilable. The pure wine of the reasoning faculty reaches the consumer only after being adulterated by the process of rebottling in successive editions of textbooks. Hence examinations are, in the true sense of the term, the morning after the night before. This explains, too, the discrepancy which has been found to exist between the results of intelligence tests of the matrix type and the results of the basic and preclinical examinations. The former are tests of inborn mental capacity alone, while the latter are tests of inborn mental capacity with its natural development often warped by clumsy and uninspired direction.

Let us, however, take medical examinations as we find them and consider their purpose and nature. Their purpose is to ensure that the student has acquired enough proficiency to pursue his vocation to the benefit of the community. This purpose is fulfilled by the final examinations directly, but by the earlier examinations only indirectly, since these do no more than ensure a knowledge of groundwork believed to be necessary for the appreciation of the final subjects. Owing to this difference in their purpose the preclinical (including the basic) examinations differ from the clinical in their character. First, the preclinical are concerned with subjects to which candidates do not intend to devote themselves. What is to their examiners a life-study is for them only a stage to be hurried through impatiently. Their knowledge is only elementary, and question and answer are cut-and-dried. Clinical examinations, on the other hand, are concerned with subjects which candidates intend to pursue as their examiners do. The examiners are chosen from teachers between whom and the candidates there exists a community of thought rarely experienced at the preclinical stage. Teachers and students, though poles apart in experience, have approached problems together and the students have followed the processes of thought going on in their teachers' minds.

Secondly, while in the preclinical examinations the subject-matter is sharply defined, in clinical examinations there is always the element of doubt. In the former, candidates have a legitimate grievance if there is any ambiguity as to the answer; in the latter they have none. While a physiologist has no right to show a candidate a badly stained slide, a physician has a perfect right to show him a patient who cannot express his symptoms clearly. In practical preclinical examinations, although examiners may avow that they want correct methods rather than correct results, the nature of the experiments is such that the results are a test of the correctness of the methods. In clinical examinations, on the other hand, methods really are more important than results. There is room for wide disagreement about medical treatment and there may be doubts even about diagnosis, though this rarely happens because the examiner enjoys the advantage of having had his own diagnosis confirmed in a pre-view by his colleagues. One wonders what would happen if clinical cases were as fresh to the examiners as they are to the candidates.

Medical examinations are of four kinds: written, practical, theoretical-oral, and clinical-oral.

The Written Examination

The written examination is the best test of systematic knowledge, since it gives the student time to express his knowledge in his own way, to amend what he has written, and to insert afterthoughts undisturbed by criticism or interrogation. Complaints about unfair questions are rare. This is because great care is taken in their composition, and because in a subject which changes but slowly at the undergraduate level questions must in some degree be stereotyped. The commonest fault consists in setting papers which are too long. This results in good candidates spreading themselves over some questions to the neglect of others. It is very difficult to convince students that if they answer only four questions out of five they automatically reduce their potential maximum by 20%. It is giving

away no secret to say that in most pass examinations the higher marks are more difficult to score than the lower in almost geometrical progression. The time spent in polishing an answer so as to make it worth 8 instead of 7 out of 10 is better spent in scoring the lower marks on another question. Question-papers are more effective in distinguishing between good and bad candidates if they err on the side of brevity.

The Practical Examination

Practical examinations should satisfy three criteria. First, the conditions of the experiments should resemble closely the conditions obtaining in normal practice. They should be as free as possible from artificiality. Secondly, if the procedures are simple or are based directly on standard scientific truths they should be performed without books; but if they are of a complex nature involving a succession of operations and a knowledge of quantities, book-directions should be allowed. Such assistance does not mar their value as tests of proficiency. Thirdly, no experiment should be set which contains an element of chance. It is arguable that careful supervision of class-work should make practical examinations unnecessary, but, students being what they are, these examinations provide a better incentive than anything else which can be devised. All the same, it is a good practice to allow candidates to produce at examinations attested records of their class-work.

The Theoretical-Oral

By theoretical-oral I mean an examination where the candidate sits in front of the examiner and answers questions on book-work without the opportunity of giving demonstrations. This type of examination seems to me to serve no useful purpose. It is supposed to enable the examiner to cover more ground than can be covered in the papers, but this is achieved only by flitting about from one part of the subject to another—a practice which puts a premium on knowledge that is merely superficial. If half an hour is considered necessary for answering one question on paper it is clear that, even allowing for the greater speed of the verbal answer, very little substantial ground can be covered in an oral of 15 or 20 minutes—a period which a candidate experienced by previous failures can skillfully reduce by saying that he doesn't know the meaning of the question. Moreover, the candidate is at a great disadvantage. He cannot arrange his thoughts except under the examiner's eyes, and if the examiner happens to start with a question on which he is weak he has great difficulty in recovering himself, knowing all the while that his fate will be sealed when the bell rings. He may repudiate a statement, but he has no assurance that he has expunged from the examiner's mind the impression which his mistake has made. There is a belief that an examination of this sort provides an opportunity for asking questions which are of the nature of riders. But when such questions are asked the candidate looks up to the ceiling in silence. Then, after appearing to say to himself, "Ah, I remember! That's on the top of the right-hand page," forthwith delivers himself of a torrent of textbook stuff. Theoretical-orals are necessary only for testing the capacity for making rapid decisions in emergencies, such as the treatment of an epileptic fit. Apart from this use they should be abolished, their place being taken, if necessary, by additional papers.

The Clinical-Oral

The clinical-oral tests observation, judgment, and logical thought as no other examination can, and it provides the best means of estimating how candidates would acquit themselves in a position of responsibility. It is therefore the ideal form of examination for clinical subjects, and should be regarded as of far more importance than papers. From the candidate's point of view it has the advantage over the theoretical-oral that the object which he is required to study shades him, at least initially, from the (to him) fierce glare of the examiner's eyes, and gives him time to adapt himself to his surroundings.

Like witnesses in court, candidates are liable to the mistake either of saying too little or of saying too much. If every word has to be dragged out of them the examiner cannot cover sufficient ground, while if they say too much they risk making a mistake which they need not have made but upon which the examiner may fasten to their discomfiture. But the worst fault is hedging—a vice calculated to drive the most angelic examiner

into a fury of exasperation. Risks must be taken in orals as in other situations, and he who refuses to take them deserves what he gets. Hedging is usually inborn, but not always: it may be the result of an unfortunate experience at a previous attempt. There are some examiners who preserve a non-committal blandness of manner or display affable agreement, giving the candidate no indication of the correctness or otherwise of his answers, and allowing him to build up an argument on a false premise. When afterwards informed of his failure he says, "I don't know why I failed; I thought I answered everything correctly." He spends the next few months in perpetual uncertainty as to whether he knows his work or not; and at his next attempt, imagining the questions to be more subtle than they appear, or suspecting a catch where none exists, he cannot be induced to give a straight answer to a straight question. A candidate's mistake should always be pointed out to him, and if he has acquitted himself poorly he should be given a strong hint of the fact towards the end of the interview. The information may be devastating at the time, but at least he knows where he stands, and the knowledge spurs him to more vigour for his next attempt.

Humour has no place at orals, since however innocent the joke the candidate is not in a mood to believe that it is not being made at his expense. Scorn and sarcasm are of course unpardonable, because the candidate is undergoing an ordeal and because he cannot answer back. The conduct of an oral is indeed a difficult art; it is the art of putting a candidate at his ease, grading the questions so as to bring out the best in him, knowing when to encourage him, and knowing when to pull him up. I am strongly of the opinion that it should not be learnt at the expense of candidates, and that before anyone becomes an oral examiner he should be obliged to spend a probationary period as an observer, studying examiners' methods and candidates' reactions.

Reform

No examinations can be perfect. The personal element can never be wholly eradicated, since examiners are subject to moods and whims just as much as others who sit in judgment. "A good, contented, well-breakfasted jurymen," said Mr. Perker, "is a capital thing to get hold of. Discontented or hungry jurymen, my dear Sir, always find for the plaintiff." The fact that the results are usually in conformity with the predictions of tutors may seem to show that examinations serve their purpose adequately. To say this, however, is to admit that they are but the reflection of teaching, and to assume that all is well with teaching. But now that medical education is the subject of so much adverse criticism we may well inquire into the relation between teaching and examinations. It is the old question of the chicken and the egg, but in another form: the question is not which comes first, but which, if either, ought to come first. There is no doubt that it is the examinations which now set the pace. "What sort of questions are they likely to ask us?" inquire students plaintively, to the despair of the educational purist. It has to be admitted, too, that their influence upon teaching is often far from good. The snap question-and-answer into which the theoretical-oral so easily degenerates encourages the "rag" classes conducted by junior members of hospital staffs and by the coaches. Let it not be imagined, however, that I am scornful of the coaches. Under present conditions they fulfil an essential function. It is a polite fiction of the academic beau-monde that they do not exist, but students have to visit them, for from them they obtain that warmth and satisfaction which grey-eyed Athens is too frigid to provide. The absurd practice of questioning candidates on the use of surgical instruments has stimulated instrument-makers to hold gratuitous demonstrations in their showrooms on the previous night—a form of instruction which can hardly be regarded as of University standard. Moreover, the system of combining external with internal examiners, necessary as it may be to prevent a lowering of standards and to protect internal examiners from charges of favouritism, is undoubtedly one cause of the conservatism of medical education, for it reduces the schools to a dull uniformity and prevents them from embarking on imaginative experiments in education.

Of any beneficial effect of examinations upon teaching there is little evidence. Some may find the explanation in the fact that examiners are themselves teachers, and the solution in the

appointment of examiners who are independent of the teachers. Examination by independent examiners, however, has not saved the School and Higher Certificates from adverse criticism, and in a subject so practical and individual as medicine the separation of the two functions could not fail to have a bad effect. The combination of the two functions in the same persons should indeed be a source of strength in both capacities; for examinations provide opportunities for passing judgment not only on students but on the way they are taught, and medical examiners who are also teachers should realize that they are examining themselves and each other no less than their candidates. Now that we are beginning to study medical education we shall find that examinations provide a valuable source of material with which to fertilize the educational field. Improved methods of teaching will benefit examinations, and examinations thus benefited will in turn improve medical education.

THE MEDICAL SCHOOLS

Return to Peacetime Conditions

The opening of the second year of peace finds almost all the medical schools returned to normal establishment. This is true even of the London schools, which suffered most from wartime disorganization and dispersal. In most of the schools the buildings are in full use, though in some the licence to repair is still awaited. The teaching staff is up to—or almost up to—normal strength. This holds good for the schools associated with Middlesex Hospital, Westminster, St. Mary's, and the London. It holds good also for Charing Cross, except for some buildings which are partly unused owing to war damage, and of the London (Royal Free Hospital) School of Medicine for Women, where the buildings, which were heavily damaged in the later stages of the war, are expected to be fully repaired by October. St. Bartholomew's still has 700 beds housed and staffed at St. Albans, but the school buildings are in temporary repair and the teaching staff at normal strength. At St. Thomas's one year of the clinical course is still taken at Hydestile, near Godalming, where in-patient clerking and dressing are done, but with more beds available in London this wartime expedient will cease. Guy's is back on a pre-war basis, save for the portions of the hospital destroyed by enemy action. All senior members of staff have returned, and, with few exceptions, all the junior staff. Beds are still retained at Orpington for special departments (orthopaedics, genito-urinary, and ear, nose, and throat).

Decentralization: An Adverse Verdict

It seemed worth while inquiring of the deans of the London schools whether they considered that any features of their evacuation experience should be permanently retained. The answer from one of the schools was, "No. God forbid!" and most of the others were scarcely less emphatic. The dean of Charing Cross, however, said that the corporate life afforded by a hostel had some advantages which might be beneficially retained, and that consideration was being given at his school to that subject. The verdict of the dean of the London Hospital Medical College was that, on the whole, evacuation has shown that decentralization of undergraduate medical education is not satisfactory, and that teaching can best be based on a hospital of approximately 1,000 beds, which provides as far as possible for all branches of diagnosis and treatment. It was also his opinion that anatomy and physiology should be taught in close conjunction with clinical work. Residence at a fever hospital, and possibly at a mental hospital, is desirable, but on the whole decentralization has more drawbacks than advantages.

The dean of King's College Hospital Medical School considered that there was one thing worth retaining from the evacuation experience, namely, the visitation of students to other hospitals.

The Schools outside London

At most of the provincial schools the return to normal has been more easily accomplished than in the several schools of London. At Liverpool the reduction of the curriculum from six years to five, which operated during the war, is coming to

an end; the next lot of candidates who graduate will have been at the school 5½ years, and by June, 1948, the normal six years' course will be in operation. The teaching staff at Liverpool is not quite up to normal numbers, but the school buildings, which were partly damaged by enemy action, have been restored to usefulness, even though some of the restoration is incomplete and temporary.

Manchester is for all practical purposes on a peacetime basis, and the staff is almost up to normal strength.

At Sheffield the school is in process of organizing and developing in accordance with the Goodenough report and the recommendations of the General Medical Council. The buildings here are more than fully in use, and additional accommodation is urgently needed. The teaching staff is up to pre-war level, but a considerable expansion is called for and is taking place as opportunities arise.

At the other Yorkshire school—Leeds—the members of the teaching staff who served in the Forces have, with one or two exceptions, returned, and many additional appointments have been made. Steps have been taken to restore the M.B., Ch.B. course to its normal length of five and a half years, and the transition from the shortened course will be completed next session. Until then the total number of students in the school remains below the pre-war level.

Birmingham is not yet on an entirely peacetime basis, though it is rapidly approaching that condition in the pre-medical and pre-clinical subjects. But it still has four clinical teachers in the Forces, all of whom rank as assistant clinical lecturers, and owing to this and other circumstances the school may actually be worse off for clinical teachers during the coming season than at any time during the war.

Newcastle-upon-Tyne (University of Durham) has its school buildings fully in use and its teaching staff at normal strength, with several departments undergoing expansion.

At Bristol some portion of the department of anatomy has been only partially replaced. Temporary buildings are now being erected to relieve the congestion, and entirely new buildings to accommodate at least 80 students a year (instead of the present entry of 60) are being planned and will be erected as soon as possible.

The Welsh National School of Medicine is working at normal level, and the same is true of the Scottish schools, though at Aberdeen and Glasgow the teaching staff is still not quite up to normal strength.

At Edinburgh, where many new developments are envisaged, the teaching staff is at normal numbers, but considerable increase will be necessary in the future.

More Open Doors for Women

Several of the London schools now admit a proportion of women students. Apart from the London School of Medicine for Women, which normally has about 450 students, pre-medical, pre-clinical, and clinical, and admitted 103 new students last session, University College Hospital takes twelve women students a year, Westminster will have six women students entering the pre-clinical department (at King's College) in October, St. Thomas's will break with tradition with a 15% entry of women students in 1947, and at the London Hospital Medical College women students up to 20% are expected to start the first M.B. in October of this year, and the second M.B. in October, 1947. At Charing Cross women students will be admitted when the school buildings, still partly unused owing to war damage, are restored. At St. Mary's, Middlesex, and St. Bartholomew's no women students will be taken until October, 1947, at earliest.

During the war the proportion of women students to men rose steadily at Leeds, and is now more than one to three. In spite of this increase approximately thirty applications were received last year for each place that could be allotted to women, and this session the number of applications is still greater. At Sheffield between 20 and 25% of the students are women, again a mere fraction of the applications. At Birmingham, again, women students make about one-fourth of the entry list. At Liverpool before the war the proportion was fixed at one-fourth, but during the war it reached 40% at one time; it is the intention to return to 25% as soon as possible. The number to be admitted in 1946

SEPT. 14, 1946

THE MEDICAL SCHOOLS

BRITISH
MEDICAL JOURNAL

depends upon the number of eligible ex-Forces applicants by the beginning of September. At Bristol, where 25 of the last autumn entry of 60 were women, the proportion is likely to be considerably reduced in the future. At Newcastle women are admitted on equal terms with men, though in smaller numbers. In the Welsh National School of Medicine, by the charter of the university there is no restriction on the admission of women candidates, and the same is true of Scottish schools. At Glasgow, owing to the relatively larger number of women applicants, the educational standard of the women admitted to the Faculty of Medicine is very high. At Aberdeen, where about 25 women students have been admitted annually during the war, the entry is expected to be reduced owing to ex-Forces candidates.

The West London Hospital at Hammersmith also serves a useful purpose in training women medical students. This is not a pre-clinical school, and the majority of the students come from King's or University Colleges (University of London) or from Oxford or Cambridge. Only women students have been accepted during the war years, and at present the acceptance is about 30 clinical students annually. This hospital was recognized by the University of London and other licensing bodies in 1937 as an undergraduate school, but it appears to be the policy of the University to remove recognition from this school in a few years' time in accordance with the Goodenough report, and it has been suggested that the future of the school should lie in the postgraduate field in association with the Federation of Postgraduate Medical Schools which has been instituted by the University.

Altogether, disregarding for the moment the forecast in some schools of a lowered quota of admission, it appears that there are about 500 places for women clinical students in the year's entries.

Ex-Forces Candidates

Arrangements are very general for the admission of ex-Forces candidates up to 90% of the total available vacancies; in accordance with the recommendation of the Ministry of Labour. At the London Hospital preference is given to ex-Forces candidates, both men and women, for admission as undergraduate students, and every effort is made to carry out the Government scheme for the rehabilitation of demobilized medical officers. An introductory course in elementary medicine and surgery, lasting three months, on the lines recommended in the Goodenough report, was given during the last academic year and proved a great success. Pre-medical education for "London" students is carried out at Queen Mary College (University of London), Mile End Road, and in view of the fact that this is inadequate to meet post-war demands from demobilized officers who have not taken their first M.B. from school, like scholar applicants, arrangements have been made by the London for their pre-medical education at various polytechnics. The majority of entries at the pre-clinical school at Guy's for the coming year are ex-Service men.

Westminster Hospital School not only gives the 90% priority but has doubled the number of registrar and B2 posts for postgraduate training. At St. Thomas's, again with 90% priority, a special bureau, under the control of a late member of the staff, has been maintained since the end of the war to help all old graduates returning from the Services. Several resident appointments are filled by these ex-Forces people, and about sixty, including many working for higher degrees, are attending a six months' rehabilitation course. At the West London Hospital Medical School arrangements have been made to appoint a certain small number of ex-Forces medical men to junior teaching posts.

No school mentions any readjustment or shortening of the course for ex-Forces applicants, and indeed the large majority of these people will be required to take the pre-registration course, which may add a full session to their training, and is not normally taken by the students at some schools, where the higher school certificate in physics and chemistry at recognized standard is accepted as satisfying pre-registration requirements. This is so at Leeds, where postgraduate instruction is also being provided under the Government scheme for the further training of demobilized medical officers.

Birmingham hopes to accept all suitable ex-Forces candidates who live in the Midland area. At Newcastle normal matricula-

tion requirements are not deemed indispensable provided the applicant can show that he has the ability to undertake the course. Manchester has a special examination known as the "mature matriculation" for those who have not satisfied the requirements for entry. Liverpool anticipates having about 65 ex-Forces people in the first M.B. and about eight new admissions to the second M.B. In addition about ten ex-Forces candidates were admitted or readmitted in the first and second M.B. courses during 1946, and most of these will be in the second M.B. course beginning in October. Priority is also given at Liverpool to ex-Forces applicants for postgraduate degrees and diplomas, and 90% of those accepted for the three degrees are from the Forces.

At Edinburgh, with the return of former students from the Forces, arrangements have been made to provide them with special courses and other facilities for revision of their previous work. The usual priority for admission to this school is accorded to ex-Forces applicants, but no shortened course has been instituted. At the medical school of Queen's University, Belfast, ex-Forces men and women of Ulster origin or sons and daughters of graduates have priority for admission. Ex-Forces students are also granted certain concessions in examinations; for example, it is possible for them to be credited with a pass in individual subjects of the curriculum provided they complete the examination within one year, unlike the ordinary student who is required to pass the full professional examination.

The Mechanics of Teaching

It seemed appropriate to address a question to the deans on any developments in the mechanics of teaching, such as the use of the film. A committee of the British Medical Association, under the chairmanship of Sir Lionel Whitby, is exploring the use of the film in medical education, and much preliminary work in the same field has been done under the auspices of the Royal Society of Medicine. The epidiascope and the film projector seem now to be installed in all medical schools and to be used alike in the pre-medical, pre-clinical, and clinical courses. At Westminster Hospital Medical School a visual education unit has lately been established, specializing in clinical photography and in the production of lantern slides, film-strip, and films; a film library is being formed there. From Leeds it is reported that the use of films in medical education is increasing steadily; the students there have formed, jointly with the local medical profession, a film society. Newcastle is trying to arrange a department in which photography and all aspects of visual education will be concentrated. At Liverpool, in addition to the usual methods, mechanical appliances are used in the school museum in the form of special models to illustrate physiological and pathological exhibits. But it is evident from the remarks of several of the deans that certain limitations of the film as an instrument of education have not yet been overcome, and at Sheffield it is stated that mechanical methods have not been introduced to any great extent because it is thought there is some danger of the film leading to a stereotyped and mass-produced instruction.

Developments at Some London Schools

The University of London still has the Goodenough report under consideration by the relevant University committees, and until the Senate has considered the matter it is not possible to make any general statement on future policy. One thing, however, may be said, namely, that the wartime arrangement permitting candidates to enter for the M.B., B.S. examination after a clinical course extending over thirty months instead of thirty-six months has been withdrawn in respect of all students who passed the second examination for medical degrees in, or after, March, 1945.

Some of the London schools are facing large developments. St. Thomas's, with an annual entry of some 80 students, is now back in its old home facing the Houses of Parliament. Its medical and surgical units are being re-formed and await the appointment of their new professors. The pathological department has expanded into a chair of bacteriology, and an occupational therapy department is being developed. The library plays an active part in school life, and the museum will soon be open. The future for St. Thomas's holds great changes. A new school is to be built at the corner of Westminster Bridge

and Lambeth Palace Road, with hostels for students opposite the present hospital, which is going to be largely rebuilt and extended. A new out-patient department is scheduled for early erection. All the departments for pre-medical and pre-clinical teaching will be much enlarged, with adequate facilities for teaching and research. A midwifery and gynaecological unit is to be created, and a chair of social medicine is in contemplation for a later date. Facilities exist at St. Thomas's for students to take the B.Sc. degree in their second M.B. subjects before beginning clinical work in the hospital. The academic year is divided for the pre-medical and pre-clinical periods into three terms and the clinical period into four.

Westminster Hospital Medical School, which in building and equipment is the newest in London, has at the moment 130 male students (clinical); this number will be increased to 150 in 1947-8, and to 200 by 1951-2. The latest entry is 24. Long-term plans include affiliation with St. Stephen's, an L.C.C. hospital with 700 beds, for an increase in clinical facilities generally, with the Infants Hospital (100 beds) for the teaching of paediatrics, with the Grosvenor Hospital (58 beds) for the teaching of diseases of women, and with the Gordon Hospital (40 beds) for the development of teaching in rectal diseases. These last three hospitals are all in Vincent Square, within five minutes' walk of the hospital.

The entry at *Charing Cross* is at present 30 a year, but when the school buildings are fully in use it will be 45. Fevers is the only subject taken extra-murally. Plans are now in an advanced stage for the rebuilding of the school and hospital at Harrow. The repairs which are proceeding will enable the instruction in the pre-clinical subjects of anatomy and physiology to be resumed at Charing Cross—a development which is regarded as of the very greatest importance.

At *St. Bartholomew's* the latest entry is 125. Arrangements for pre-medical students are now the same as before the war. Certain long-term plans are set out in the report of a Policy Committee, but the main immediate objectives are, first, the permanent rebuilding both of the damaged hospital and college, and, secondly, the establishment of additional whole-time chairs to enlarge the teaching in clinical subjects, for example, therapeutics and radiotherapeutics.

Middlesex Hospital has its buildings fully in use and can take 80 students annually. Students are admitted to the recognized courses of study for the first M.B.

London (Royal Free Hospital) School of Medicine for Women, with an annual entry of 100, is resuming its pre-medical course at the school itself as in pre-war times. During the war, and until the present session, its physiology and organic chemistry departments enjoyed the hospitality of Guy's.

St. Mary's, Paddington, has an annual entry of about 66. Here again the arrangements for pre-medical students are as before the war. The long-term plans include rebuilding and expansion to an annual entry of 100.

King's College Hospital, Denmark Hill, which is now wholly a peacetime basis, with its teaching staff up to normal, takes between 50 and 60 new students each year. The future long-term plans make provision for 100 new students in a year. Women students have been admitted to King's College Hospital since 1917. The pre-medical and pre-clinical students receive their education at King's College, Strand. It is hoped that practically all the clinical students will have returned to Denmark Hill in October, 1946, when courses on a pre-war basis will be held.

Guy's pre-clinical school has been working to capacity during the year, and the majority of the entries for the coming year are ex-Forces men. Applications for admission have been heavy, but acceptances are limited by accommodation available.

St. George's Hospital Medical School at Hyde Park Corner has returned to normal; indeed, its teaching staff is above pre-war strength. This is one of the small schools, and "all the better for that," thinks the Dean. Its students at any time number not more than 120, which means an entry of about 30 a year. Women students at present represent 10% of the entry; in 1948 they will represent 15%. The school takes students from Oxford and Cambridge, and a few from other universities, but the majority of the remainder come from London, and almost entirely from King's College. At the present time fevers and obstetrics are taken extra-murally, but by the end

of the present academic year fevers only will be taken in that way. As for long-term plans it is well known that St. George's Hospital is to be rebuilt in another quarter of London—the south-west. The number of beds will be increased, but the principles of the Goodenough report will be adhered to—an entry of 100 students for 1,000 beds. At present there is an entry of 30 students for 350 beds. "The difficult thing we are trying to do at St. George's," said the Dean, "is to reconcile the tradition of a rather intimate small school with the enlargement of the hospital, and one thing we are resolved upon is never to take in more students than the number for which clinical cases can be provided. We feel that the actual contact of the student with the patient is all-important in medical education."

London Hospital Medical College takes 80 medical students a year, and this year the maximum number has been accepted. The rebuilding of the dental school (25 students a year) is the first priority, and reconstruction of the whole medical school and hospital the long-term plan. There is a hostel for 100 students, to be enlarged as soon as possible.

University College Medical School has arranged to increase its entry by 5%, bringing it to the maximum which can be taken with the present accommodation. The medical course is being revised to conform to the General Medical Council's proposals (36 months). Fevers and some obstetrics are taken outside the hospital. Pre-medical students are accommodated at University College and at Oxford and Cambridge. Future long-term plans include the extension of the school and hospital (1,000 beds) to take an annual entry of 100.

West London Hospital Medical School, although one hospital ward has still to be reopened, has more teaching beds available than ever before, thanks to the association with Fulham Hospital (L.C.C.). The only subject taken extra-murally is obstetrics, at the West Middlesex Hospital; demonstrations are given at special hospitals, especially in mental disease.

Post-war Policy at Oxford and Cambridge

Oxford.—The number of students to be admitted to the Oxford University medical course in 1946-7 is limited by decree of the University, which restricts the entry from schools to 55 men and 10 women, as well as by the regulation of the Ministry of Labour and National Service concerning preference for ex-Forces candidates. Owing to the limited number of places in the medical school a prospective student, after he has been accepted by a College, must be considered and accepted by the University committee set up to select the students making up the quota for the year. After this he is eligible to go into residence and is qualified for admission into the medical school, and thereby for deferment; subject to satisfactory reports of progress, by the Joint Recruiting Board, to which, if he was born after Sept. 30, 1928, he must have made application with his appropriate age group. Oxford is almost back to a pre-war basis, though the Honour School of Physiology is not compulsory for ex-Forces men matriculating before October, 1948. The school can take an annual entry of 70 to 80 for the pre-clinical period, and 25 for the clinical. The latest entry is 46 men from the schools, and 10 women. The number of ex-Forces students accepted outside the quota is not yet determined, but will probably be about 30. Future long-term plans include a new physiology laboratory, extended instruction in social medicine, and improved hospital service and facilities for clinical students.

Cambridge.—The general post-war policy at Cambridge University is to maintain the pre-clinical teaching at its previously high level and to develop a school of clinical research and postgraduate teaching both in specialties and in general medicine, rather than to attempt to found a complete undergraduate school. This is in accordance with the recommendations of the Goodenough report. Plans for postgraduate work have begun to materialize with the reopening of the department of medicine and the creation of a chair of experimental medicine and a chair of radiotherapeutics. Other special departments which are contemplated include paediatrics, dermatology, social medicine, and chemotherapy. In all these special departments there will be opportunities for research students and for training for long or short periods. In general medicine the experience gained with ex-Service postgraduate courses has indicated the need, for the future, of regular courses for

Medical practitioners are invited to apply for their copy of this new booklet which has been especially written as an up to date guide to the principal indications for penicillin therapy.

Only references to recent articles in British, American and Dominion medical journals have been included. The booklet is conveniently divided into sections dealing with the properties of penicillin, its indications, the methods of administration and dosage, clinical reports, and, in conclusion, its presentation.

MEDICAL DEPARTMENT

BOOTS PURE DRUG COMPANY LIMITED
STATION STREET NOTTINGHAM

'PALUDRINE'

A Potent Antimalarial

The results available from extensive clinical investigations which are proceeding with 'Paludrine' both in this country and in malarious regions abroad show that this new drug is a highly efficient antimalarial with definite advantages over mepracrine and quinine.

- 'Paludrine' controls the clinical symptoms of all forms of malaria and terminates the attack.
- It is a true causal prophylactic in malignant tertian malaria, and a partial causal prophylactic in benign tertian malaria.
- It produces a radical cure in malignant tertian malaria. In benign tertian malaria, following treatment of the acute attack, relapses may be controlled indefinitely by the administration of one tablet (0.1 gramme) once a week.
- It is extremely well tolerated and in normal dosage it does not produce unpleasant symptoms of any kind. Furthermore, it is colourless, and there are no aesthetic drawbacks to its use.

THE RIDGE, BEECHFIELD ROAD,
ALDERLEY EDGE, MANCHESTER

Ph. 156a

(Ascorbic Acid)

There is increasing evidence that vitamin C plays an essential part in most of the processes of protein metabolism in the body. It is associated with the growth, renewal and structural maintenance of connective tissues, the organic matrix of bones and teeth, formation of red blood cells and hæmoglobin and possibly with the formation of antitoxins and antibodies, thus playing a part in protecting the body from infection and anaphylaxis.

Vitamin C B.D.H. is available for oral and parenteral use in tablets and ampoules in strengths suitable for prophylactic or curative treatment for all the purposes indicated above. Further details are available on request.

The Modern Surgical Dressing

'Elastoplast' is valuable in the treatment of sprains, wounds, and varicose conditions. As a dressing, it affords protection to newly-formed granulations, and should be allowed to remain undisturbed as long as possible, provided no unusual pain is experienced.

Elastoplast
BANDAGES AND PLASTERS

Made in England by T. J. Smith & Nephew Ltd., Hull.

REMINDER: Smith & Nephew Plaster of Paris Bandages now carry the universal Trade Mark 'GYFSONA'

For the GROWING CHILD

To supplement the diet during childhood and adolescence, 'Kepler' Cod Liver Oil with Malt Extract provides a standardised content of vitamins A and D together with readily-assimilable fat and carbohydrate in an attractive and palatable form. 'Kepler' contains not less than 23 per cent v/v of fine-quality standardised cod liver oil. Each fluid ounce provides not less than—

Vitamin A 3,500 International Units
Vitamin D 500 International Units

'KEPLER'

COD LIVER OIL WITH MALT EXTRACT

general practitioners of scope and length adapted to their various needs. An essential part of this organization has been the creation of a closer liaison between Addenbrooke's Hospital and the University. The first step in this direction has been the assumption of responsibility by the University for the pathological and biochemical services of the hospital. In the same way it is contemplated that other services will come into close association with the University, including the regional laboratory services and a co-ordinated regional scheme for orthopaedic, thoracic, and neurosurgery. All these plans are designed to make the University the focus of medical research and teaching for the East Anglian region.

The Northern Schools

The annual intake of students at *Leeds* is limited to 85 in the first year, but to 75 in the second year; a larger number cannot be accommodated in the department of physiology, where the classes have for some years been held in duplicate. Immediate activities include the revision of the curriculum in accordance with the G.M.C.'s recommendations. The establishment of full-time chairs in medicine, psychiatry, and paediatrics has been approved and appointments have been made, and the position regarding surgery and obstetrics and gynaecology is under consideration. New chairs have been instituted also in chemical pathology, biochemistry, and pharmacology, and the administration of the school has been strengthened by the appointment of a medical man to a new post of senior administrative officer. Long-term plans include further increases in staff, the establishment of further new departments and sub-departments, the building of a new medical school, and the full utilization of the municipal hospitals for teaching purposes. A general need is the provision of more hostel accommodation.

Sheffield has an entry of about 50 a year at the present time, but hopes to increase it to 80-100 within the next few years. The arrangements for the pre-medical students require the courses in chemistry, physics, and biology to be taken in the University, except in very special circumstances. The long-term plans at Sheffield include a new medical school and teaching hospital, the appointment of a full-time dean, and generally development along the lines of the Goodenough report. At Sheffield, as at Leeds, the need for more halls of residence is felt.

The Medical School at *King's College, Newcastle-upon-Tyne* (University of Durham) can accommodate 380 medical students and 155 dental. The figures for the latest entry are not yet available owing to the recent Government regulations concerning ex-Forces candidates. The normal medical course is now reinstated to the full period of six years after the wartime adjustment. The pre-medical course may be taken in the University, and "first year" students sit the first M.B. examination after one year's study. In addition certain schools are recognized by the University for the purpose of instruction leading to the first M.B. Exemption may be granted from the first-year course and examination if the candidate has obtained the necessary higher certificate qualifications. At Newcastle whole-time chairs have been established in the departments of child health, surgery, and industrial health, and it is hoped to institute similar appointments in medicine and psychological medicine. Plans are also under consideration for the establishment of a department in anaesthetics under a reader.

Liverpool.—The number of student admissions to the Faculty of Medicine at Liverpool is limited at present by bench space. The limit has been put at 100 a year in the second year. The admissions for the first year of study are limited at present by the Faculty of Science to 70, and the number admitted directly into the second year is therefore determined by the number passing up from the first year. But there is no definite limit to the number admissible to the clinical school, and students from Oxford and Cambridge are often admitted after their pre-clinical years. Postgraduate students admitted during the past session numbered about 80, of whom 23 were for the D.P.H. For 1946-7 there will be larger numbers in the courses reading to the D.P.H., the M.Ch.Orth., and the new Mastership in Radiology. Pre-medical courses are covered by the first M.B. examination taken internally in the departments of physics, chemistry, zoology, and botany of the University. In addition the University of Liverpool, during the war, has accepted the

higher school certificate of any British Examining Board with passes at principal standard in physics, chemistry, and biology (or zoology and botany taken separately) as exempting from the first M.B. This wartime exemption on higher school certificate is still in operation.

Long-term plans at Liverpool are largely conditional on rebuilding, the accommodation being strictly limited. Future policy in respect of the curriculum will be reconsidered when the G.M.C.'s report on the subject is made public. Associated with the Medical School in the Faculty of Medicine are the School of Tropical Medicine, the School of Dental Surgery, and the School of Veterinary Science, all of which are undergoing increased development at the present time. The Medical School embarked on several new ventures during the war and contemplates others in the near future. A large and important department of child health has been constituted under a half-time director, who is also Professor of Child Health. This department has been granted special facilities and accommodation not only in the Royal Liverpool Children's Hospital, but also in the municipal hospital for children. A department of neurology with a professor in neurosurgery has been approved, and the appointment of the professor will be advertised shortly. Last year the University appointed its first full-time professors in clinical subjects, namely, in surgery and in obstetrics and gynaecology, and these departments are now in full swing and are undertaking considerable postgraduate activities, both in respect of the training of specialists and in research.

The *University of Manchester Faculty of Medicine* can take between 90 and 100 students per session. Pre-medical students are admitted in the normal way. Among the amenities of the school is a first-class physical education centre. A new department of industrial medicine was instituted at the University last year, and a chair has been founded in association with it. A dean of post-graduate medical studies was recently appointed with a committee to help him.

The Midlands, West of England, and Wales

Birmingham.—The Medical School at the Hospitals Centre, Birmingham, is designed to take 60 medical students a year, but this number is being increased in the near future to 120. This increased number will mean the duplication of many classes, particularly in pre-clinical subjects, and an increase in the staff. The latest entry is between 80 and 90. The majority of students take their pre-medical course at school, and rather more than a third of the number take the pre-medical course at the University. The readjustment of certain courses is contemplated, and in particular there is being started next year a preliminary instructional clinical period consisting of integrated classes in medicine, surgery, pathology, and pharmacology, as recommended in the Goodenough report, the course taking three months immediately after the examination in anatomy and physiology. Full-time professors in medicine, surgery, midwifery, and gynaecology, and in paediatrics and child health have recently been appointed, and the occupants of these chairs will take up work at the beginning of the next session. During the last year liaison between the preventive medical services and the City of Birmingham in connexion with child health and the Children's Hospital has been brought about. Close association with civic work is also maintained in the Department of Social Medicine and it is hoped that the clinical facilities of the municipal hospitals will be made available for students in the future.

Birmingham receives about 600 applications for the vacant places in the school and a number of these are from students overseas. It has undertaken to admit a certain proportion of colonial students, but with the limited accommodation it is unlikely that other overseas students can be admitted.

The *University of Bristol Medical School* takes an entry of about 60 students a year. The curriculum is now on its pre-war basis, the wartime shortening of the clinical period having been brought to an end. Pre-medical students are given special courses for the first M.B. Several have exemption from this examination by obtaining a higher school certificate in the subjects concerned.

The school has lately made arrangements for the reintroduction of the course for the D.P.H. It has also instituted diplomas in psychological medicine and in medical radiology and a certifi-

cate in public health. In addition, during the coming session, it is expected that a course will be arranged for the diploma in physical medicine.

The *Welsh National School of Medicine* at Cardiff continues to teach students mainly for the degree of M.B., B.Ch.(Wales). For admission to this degree candidates must possess a degree in arts or science normally involving three years' residence in the University College of South Wales and Monmouthshire before entering the school. During the war this requirement was suspended for those students entering the college who had been exempted from the pre-medical courses and examinations. The number of students admitted is governed by the available accommodation both in the college and the school, and is normally between 40 and 50. Any loss during the pre-clinical years is made up by the admission of a certain number of students to the school from other universities who are studying for qualifications granted by other licensing bodies. For the forthcoming session the University of Wales, like others, is required by Government decision to give absolute priority to ex-Forces applicants who are academically qualified for admission, and it is anticipated that few students, men or women, will be admitted direct from the schools. The school, jointly with the Cardiff Royal Infirmary, has formed a Future Policy Committee, which has under consideration the establishment of a university medical teaching centre, with a teaching hospital of 1,000 beds and providing for an annual intake of 100 clinical students.

The postgraduate courses for C.P.H. and D.P.H.(Wales) under the new rules of the General Medical Council are being conducted, and those for the tuberculous diseases diploma (Wales) are being resumed this session. The school is administering for the Ministry of Health the scheme for postgraduate training of demobilized medical officers. The placing of Class I officers in hospitals creates a little difficulty in finding resident posts for recent graduates, but an effort has been made to retain a sufficient number of vacancies for them. It is anticipated that this difficulty will not be of long duration and will not affect those now entering upon their studies.

The Scottish Schools

Edinburgh.—Very large numbers of candidates still apply for admission to the Medical School of the University of Edinburgh; last year the applications numbered 900, and this year they have reached the figure of 1,500. Approximately 200 new students are admitted in October of each year. Normally applications for admission must be submitted not later than July 1 of the year in which the student wishes to begin the medical course. Medical students in Edinburgh University undertake the full course of instruction, including the pre-medical subjects of physics, botany, chemistry, and zoology, in the medical school. The long-term plans at Edinburgh include broadly the extension on a large scale of accommodation and facilities for teaching and research and the establishment of hostels for students.

During the war Edinburgh afforded a home for the Polish School of Medicine. This school is still functioning in Edinburgh, but no decision as to its future has so far been reached.

Surgeons' Hall, the school of medicine of the Royal Colleges of Edinburgh, is a teaching body only; it offers courses for the qualifying examinations of the Conjoint Boards. The maximum number admitted in the first year is 72—a total of 360. After October, 1947, a pre-medical year of study will be introduced.

Glasgow.—The Faculty of Medicine of Glasgow University admits 180 students every year to first-year medicine and, in exceptional cases, a small number directly to the later years of the curriculum. Applications for admission to the Faculty have to be made during the last fortnight of May, for entry in the following October. Selected candidates are summoned for interview by the Selection Board, usually in July, but special arrangements have had to be made this year in view of the priority given to ex-Forces candidates. All entrants are required to possess the Scottish Universities Entrance Board Certificate of attestation of fitness, which is issued on the results of the candidate's school-leaving certificate. The curriculum in medicine at present extends over five years, but it is likely

that a six years' curriculum, which was ready to operate in 1939, will soon be brought into force. This new curriculum will first be reviewed in the light of recent official recommendations. The curriculum has not been shortened during the war, but the dates of the final examination have been changed, which has had the effect of enabling students to graduate in a minimum period of four years and nine months without reducing the period of instruction. This arrangement is being continued for the present.

At Glasgow four large general hospitals are associated with the University for the teaching of clinical medicine and surgery. Clinical obstetrics and gynaecology are taught mainly in the Royal Maternity Hospital, and paediatrics in the Royal Hospital for Sick Children, while special subjects are taught in the appropriate departments of the numerous hospitals in the area. In addition a large amount of postgraduate teaching is undertaken, and this is to be enlarged.

The Glasgow University General Bursary Examination is held in June and is open to men and women applying for admission to the Faculty of Medicine. The examination is on a competitive basis and about twenty bursaries in medicine are available each year.

Anderson College of Medicine at Glasgow and St. Mungo's College are extra-mural schools, offering courses in preparation for the examinations of the licensing boards and universities. Anderson College has an annual intake of 30 medical and 50 dental students. Here also 90% of admissions are reserved for ex-Forces people. The buildings of St. Mungo's are in the grounds of Glasgow Royal Infirmary.

The Faculty of Medicine of the University of *Aberdeen* takes about 95 students a year. The course in Aberdeen is a single course; there is no pre-registration. The curriculum was rearranged just before the war and now covers seventeen terms. The buildings in which the training during the three final years is taken are on a site common to the University and the hospitals.

The University of *St. Andrews* reverted to the peacetime pattern of examinations in 1944, and since then students have been taking their final examinations after 33 months of clinical study, instead of the wartime 30. The school takes 75 students a year. Here again the pre-medical subjects are taken within the University. The school contemplates a long-term policy of expansion in which the Dundee Royal Infirmary will be joined.

Ireland

Belfast.—The Faculty of Medicine of Queen's University, Belfast, draws the majority of its students from the North of Ireland, though there is usually a fairly good admixture from the Dominions, the Colonies, and foreign countries. There are certain priorities for entry, the first being local candidates, sons and daughters of graduates, and applicants from the British Commonwealth. There has been a limitation of the annual number of entrants since 1939 to 112, but as a special concession to those discharged from the Forces the number has now been raised to 130. The entry for 1946 has filled all available places, and well over 100 applicants have had to be refused. The only change in the curriculum has been the continuation of the wartime reduction of the six-year course to five and a half years, but from October next the six-year course will again obtain. Students are generally accepted only for the complete course. Applicants are required to pass University matriculation and also the pre-medical examination in chemistry and physics.

With increased grants there has recently been an extension of the medical staff. The chairs of medicine and surgery have been made full-time chairs with limited practice. The professors will be full members of the honorary staff both of the Royal Victoria Hospital and the Mater Infirmary. Lectureships in embryology, histology, applied pathology, and pharmacology, and tutorships in medicine, surgery, and obstetrics, as well as a number of positions of registrar in these subjects, have been established. It is intended to rebuild the clinical departments of the school, to expand the Institute of Pathology and the departments of anatomy and physiology, and to increase the laboratory facilities for research generally. A new curriculum, based upon the recommendations of the Goodenough report but using to the best advantage the local facilities for teaching

and research, comes into effect in October. Clinical studies are pursued at a number of teaching hospitals associated with the University, and altogether over 1,200 general hospital beds are available. Various special hospitals are also recognized by the Faculty. Three hospitals concerned with ophthalmology and otolaryngology have recently been fused into one centrally placed hospital.

Plans for the development at Belfast of a postgraduate school are under consideration. At present the postgraduate facilities are being used to the full in the rehabilitation of ex-Forces graduates, of whom 650 are now taking or awaiting them.

Dublin.—The courses and examinations leading to the degrees in medicine, surgery, and midwifery in Trinity College, University of Dublin, proceed as usual. The University is offering a diploma in obstetrics, for which a course is held at Trinity College and at the Rotunda.

The University Colleges of Dublin, Cork, and Galway are constituent colleges of the National University of Ireland. The work in the medical schools here also is proceeding as usual.

The Royal College of Physicians of Ireland grants to registered medical practitioners, after examination, licences in medicine and midwifery and membership of the College. Fellowship is by election from the members.

The Royal College of Surgeons in Ireland has under its direction the Schools of Surgery, including Carmichael College and Ledwich School. Together with the Royal College of Physicians of Ireland it grants a conjoint licence in medicine, surgery, and midwifery, a final registrable qualification.

THE MEDICAL REGISTER

Numbers Entering the Profession

The General Medical Council, the full title of which is the General Council of Medical Education and Registration of the United Kingdom, constituted under the Medical Act, 1858, is not an examining body. Its special function in medical education is to ensure that in the various schools and licensing bodies certain minimum standards of teaching and examination are required. This is done by means of recommendations and the visits of inspectors. The Council is responsible also for the discipline of the profession, an activity which brings it more prominently to the notice of the public, but its task in laying down the standards required for admission to the *Medical Register* is at least of equal importance.

A qualified medical practitioner is required to register with the General Medical Council before he is permitted to practise his profession. The names appearing in the *Medical Register* for 1946 number 75,133, of which about 47% are registrations in England, 27% in Scotland, and 13% in Ireland; 7% are colonial registrations, and 0.5% foreign. In addition 5.5% (comprising 4,168 names) are temporary colonial and foreign registrations, relating to persons temporarily registered in pursuance of the Medical Register (Temporary Registration) Orders, 1940 and 1941, made under Defence Regulation 32B. This number is now diminishing.

The number of names in the *Medical Register* on Jan. 1, 1946, was the largest ever recorded, being 1,487 more than on the corresponding date of 1945, 3,251 more than in 1944, 3,500 above the average of the last five years, and some 14,000 above the average of the last twenty. The number of persons on the *Register* in 1932 was only three-fourths of what it is at present.

At the beginning of the present century the number of newly qualified persons registered each year was about 1,300. During the war of 1914-18 it went up to 1,500, and in 1924 it suddenly rose to 2,800, this figure being the result of the greatly increased entry of students at the end of the war. It fell again in 1930 to 1,500, and subsequently it gradually crept up, rising consistently almost every year until 1942, when it reached a peak at 3,556. Since then the numbers have fallen, and for the year 1945 the number of new registrations was 2,666.

There is an annual wastage by reason of death of about 1,100 from the *Medical Register*, and anything from 50 to 80 names are removed annually under various sections of the Medical Act. The numbers added by registration during the

years since the beginning of the war, the numbers removed, and the state of the *Register* on December 31 of each year are set out in the following table:

	New Registra- tions	Removals	Names left on <i>Register</i>
1939 ...	2,968	1,027	63,360
1940 ...	2,384	1,102	64,679
1941 ...	3,296	996	66,992
1942 ...	3,556	1,127	69,428
1943 ...	3,532	1,091	71,882
1944 ...	2,971	1,218	73,646
1945 ...	2,666	1,190	75,133

Students' Registration

The number of students admitted to the medical schools in Great Britain and in Eire in 1945-6 is estimated by the General Medical Council to have been 2,610. This is almost identical with the actual number for the previous year (2,612), and above the average for the war years (2,480). The student entry in recent years has been as follows:

1938-39 ...	1,735	1942-43 ...	2,468
1939-40 ...	2,623	1943-44 ...	2,426
1940-41 ...	2,398	1944-45 ...	2,612
1941-42 ...	2,361	1945-46 ...	2,610

(estimated)

The figures of recent years accord with the Goodenough Committee's recommended entry of 2,500 to 2,600 as being desirable at present.

The address of the General Medical Council is 44, Hallam Street, London, W.1.

EXAMINING BOARDS

The English Conjoint

The Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of L.R.C.P., M.R.C.S. Copies of the latest emergency regulations, issued in May, 1946, may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, London, W.C.1.

Four examinations have to be passed—a preliminary examination in general education recognized by the Board; a pre-medical examination conducted or recognized by the Board; a first examination in anatomy, physiology, pharmacology, and materia medica conducted or recognized by the Board; and a final examination in pathology and bacteriology, medicine, surgery, midwifery, and gynaecology. Candidates are required to complete the medical curriculum extending over not less than 54 months of study at recognized medical schools and hospitals, and to pass the professional examinations in accordance with the regulations after passing any two parts of the pre-medical examination. The examinations of the Board are conducted four times a year, and candidates are required to give notice in writing to the secretary of the Board twenty-one days before the examination. The Board does not itself conduct the preliminary examination in general education, but recognizes for the purpose a number of matriculation examinations conducted by, and entitling candidates to enter, the medical faculty of a recognized university, also the possession of certain school-leaving certificates.

The subjects of the pre-medical examination are chemistry (inorganic and organic), physics, and biology, including the elements of genetics. The first medical examination is in two parts: the first, anatomy (including histology and embryology) and physiology, being written, oral, and practical; and the second, pharmacology and materia medica, being oral only. In the final examination, in pathology, medicine, surgery, and midwifery and gynaecology, the second, third, and fourth parts are written, clinical, practical, and oral: the first part, pathology, is written and oral only, and may not be taken alone as the last part of the examination. The other parts may be taken in any order. Candidates who produce evidence of not less than 24 months' recognized clinical study subsequent to passing in anatomy and physiology are admissible to any one part

only of the examination, subject to production of certificates. On the completion of 27 months of recognized clinical study candidates are admissible to one or two further parts, or, if presenting themselves for the first time, to three parts, subject again to the production of the necessary certificates. Candidates may not enter for the last part of the examination until they have completed 30 months' clinical study.

Before being admitted to the final examination candidates have to produce evidence of having attended certain specified courses at a recognized medical school and hospital; of general out-patient and in-patient attendance at a hospital during 30 months, six months' medical clinical clerkship, six months' surgical dressership, and three months' gynaecological clerkship; of attendance at five labours by a teacher or member of the staff of an approved hospital, and of having subsequently conducted 15 other labours; of having received instruction in children's diseases and the care of infants, and in the eye, throat, nose and ear, and skin departments of general hospitals or at special hospitals, and of having received instruction in venereal diseases, radiology, and vaccination, and of having attended courses, including clinical demonstrations, at a fever and at a mental hospital. Finally—what cannot be very difficult in view of the length of this discipline—the student must show that he is at least 21 years of age.

The Scottish and the Irish Conjoint

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement whereby the student may obtain after one series of examinations the diplomas of all three bodies. Candidates for the examination of the Scottish Conjoint may work at any of the medical schools of Great Britain and Ireland. Details may be obtained from the registrar, 18, Nicholson Street, Edinburgh, 8.

The Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland issues a joint licence in medicine, surgery, and midwifery, and accepts candidates from most of the medical schools at home and overseas. The regulations can be obtained from the registrar, Royal College of Surgeons in Ireland, Dublin.

Apothecaries' Licences

The Society of Apothecaries of London grants the diploma of licentiate in medicine and surgery (L.M.S.S.A.Lond.) to candidates who pass in the primary examination, which is held quarterly, and the final examination, which is held monthly, except in September. The minimum period of study is normally five years. Further information may be obtained from the registrar, Apothecaries' Hall, Blackfriars Lane, E.C.4.

The Apothecaries' Hall of Ireland (95, Merrion Square, Dublin) grants the L.A.H.Dubl. to students who pass the professional examinations.

UNIVERSITY DEGREES

All the universities offer bachelor degrees in medicine and surgery, conferred on the results of examination. All the universities also confer on graduates holding a bachelor's degree the higher qualification of doctor of medicine or master of surgery. The requirements vary, and particulars should be obtained from the different universities. The degree of doctor of surgery, in addition to that of master of surgery, is offered at Durham. Liverpool offers the degree of master of orthopaedic surgery. The University of Dublin, the National University of Ireland, and Queen's University of Belfast offer the degree of Master of Obstetrics.

Higher Qualifications at Royal Colleges

The Royal College of Physicians of London confers its Membership (M.R.C.P.) by examination. A candidate is required to give at least 28 days' notice of his intention to present himself for examination and to transmit such medical and surgical qualifications as he may have obtained, together with a list of his public and other appointments, testimonials, etc. The pass examination for Membership consists of a written examination in the form of a paper on questions of medical anatomy, on pathology, and on the principles of medicine, a paper on questions on the practice of medicine, including the principles of public health, and on psycho-

logical medicine, a clinical examination in the medical wards of a hospital, and oral examinations. Fellows of the College are elected annually at a general meeting. (Particulars from the College, Pall Mall East, London, S.W.1.)

The Fellowship of the Royal College of Surgeons of England is granted to those passing primary and final Fellowship examinations. The primary examination is held in the months of April and October. The subjects are anatomy, including normal histology, and applied physiology, and the principles of pathology. This examination is partly written and partly oral. The final examination is held in May and November, and the subject is surgery, including surgical anatomy and pathology. This again is partly written and partly oral, and includes the examination of patients and the performance of operations on the dead body. Candidates who have passed the primary examination are admissible to the final on production of evidence of having been engaged in the acquirement of professional knowledge for not less than two years subsequent to the date of having obtained a registrable qualification, and of having held for not less than six consecutive months a recognized resident post in charge of general surgical patients in the wards of a general hospital recognized by the Council for the purpose. List of recognized hospitals is obtainable from the College, Lincoln's Inn Fields, London, W.C.2.

Membership of the Royal College of Obstetricians and Gynaecologists may be applied for by medical graduates who have been registered or eligible for registration for at least three years. The Fellowship of the Royal College is granted to members who are considered to have advanced the science and art of obstetrics and gynaecology. The address of the College is 58, Queen Anne Street, London, W.1.

Graduates may become Members of the Royal College of Physicians of Edinburgh on passing an examination, particulars of which can be obtained from the secretary at 9, Queen Street, Edinburgh, 2. It is a four-day examination—a written examination on the first day, a clinical examination on the second, on the third a practical examination with reference to the special subject the candidate has professed, and on the fourth an oral examination in medicine and therapeutics and the special subject. For the Fellowship of the Royal College it is necessary to have been for at least three years a member. Every proposal for election of a Fellow by the council of the college must be signed by four Fellows.

Fellowship of the Royal College of Surgeons of Edinburgh is granted to medical graduates who pass the necessary examination (particulars from the clerk of the College, Surgeons' Hall, 18, Nicholson Street, Edinburgh).

Fellowship, registrable with the General Medical Council as an additional qualification, is granted, after examination, by the Royal Faculty of Physicians and Surgeons of Glasgow. The candidate must be a licentiate of the Faculty or a graduate in medicine of a university or medical college approved by the Faculty, and may be examined either in medicine or surgery. Particulars from the office of the Faculty, 242, St. Vincent Street, Glasgow, C.2.

The Royal College of Physicians of Ireland grants membership on the result of an examination and elects Fellows by ballot from among the Members. The address of the registrar of the College is 6, Kildare Street, Dublin. Fellowship of the Royal College of Surgeons in Ireland (St. Stephen's Green, Dublin) is passed in two examinations, a primary in anatomy and physiology, and a final in surgery.

FACILITIES FOR POSTGRADUATE EDUCATION

Arrangements at the Universities

In describing the undergraduate arrangements at a number of schools in the foregoing account, postgraduate schemes have been incidentally mentioned. Every university in the country is making arrangements of some kind, although of course on a much smaller scale than in London, which bids fair to be the postgraduate centre of the country and indeed of the Empire (see the article by Sir Francis Fraser at p. 353). Preparations in many centres have been delayed owing to insufficiency of teaching staff, and priority has had to be given to the Government scheme for demobilized doctors, which has fully occupied the existing staff and equipment. This work is expected to have reached its peak in the present summer, and after this the facilities for postgraduate education should become available for graduates not only from this country but from overseas to an increasing extent. The experience gained in carrying out the Government scheme will itself prove of great value, both in the training of specialists and in the provision of courses for general practitioners.

The British Postgraduate Medical Federation

A little over a year ago the Senate of the University of London gave general approval to a scheme for a federated post-

graduate school as outlined in a report from the existing British Postgraduate Medical School at Hammersmith, and authorized that school to take steps to amend its constitution so as to give practical form to the proposals. Accordingly the central office of what is now known as the British Postgraduate Medical Federation was opened at first at the London School of Hygiene and Tropical Medicine, with a staff lent by the Ministry of Health, to carry out on behalf of the University of London the Government scheme for the postgraduate education of medical officers on release from the Forces. In November a move was made to No. 2, Gordon Square, London, W.C.1. Discussions were continued or newly entered upon with various hospitals in London with a view to establishing postgraduate institutes in the various branches of medicine.

Satisfactory progress was made with the Royal National Throat, Nose and Ear Hospital, the Royal London Ophthalmic Hospital, and the National Hospital, Queen Square. These hospitals have constituted their teaching schools separately from the respective hospitals, under committees of management and academic boards, and are able to provide sufficient accommodation for teaching and research to justify financial aid out of the block grant for their further development as institutes. The Institute of Laryngology and Otolaryngology began to receive financial assistance in January of the present year, the Institute of Ophthalmology in March, and the Institute of Neurology in April. The Institute of Child Health has been constituted a central activity of the University and will become a constituent institute of the Federation, as also will the British Postgraduate Medical School. St. John's Hospital for Diseases of the Skin has entered into negotiations with University College Hospital Medical School for facilities for teaching and research, so that an Institute of Dermatology may be expected to be a constituent institute of the Federation during the next academic year. Preliminary discussions have been held with the Brompton Hospital, the Heart Hospital, St. Peter's Hospital for Urinary Diseases, and the National Orthopaedic Hospital, though lack of accommodation for teaching and research makes it unlikely that specialist institutes can be formed during the next year.

It has been decided to petition for a Royal Charter for the Federation and a supplemental charter for the existing British Postgraduate Medical School. The new specialist institutes will be separately incorporated under the Companies Act.

For the training of specialists, to meet the demands of graduates coming to London, it is proposed to create "registrarships for specialist trainees" at the British Postgraduate Medical School and the special hospitals mentioned. One difficulty is that graduates may come to London at different stages in their postgraduate training, and as their capabilities and experience will be unknown to the hospital authorities they may not be able immediately to obtain suitable hospital appointments. It is proposed to provide training, including clinical experience, for such graduates, but without responsibility for the care of patients, so that it will be possible for their suitability for responsible appointments to be tested and for them to obtain such posts as vacancies occur. This would also meet the needs of those who visit London for shorter periods and do not require full specialist training. These courses of training are provided at the British Postgraduate Medical School, the Institutes of Child Health, Neurology, Laryngology and Otolaryngology, and Ophthalmology, and at Maudsley Hospital, but augmented or extended accommodation is needed. Another desirable innovation is a revision course in advanced general medicine or general surgery suitable for the specialist who has had sufficient practical experience but requires a short period of academic instruction to complete his training or to obtain a higher degree or diploma. It is also hoped to provide travelling fellowships open to graduates undergoing specialist training at the undergraduate schools as well as at the schools and institutes of the Federation, such fellowships to be held usually in the last year of specialist training.

Postgraduate Education for the General Practitioner

Under the Government scheme for demobilized doctors a series of two weeks' intensive general refresher courses for practitioners was arranged at non-teaching hospitals, voluntary

and municipal, in the London area; but it is hoped to go further and to accommodate the provision to special conditions of practice by the following methods:

- (1) Clinical assistantships requiring attendance on at least one half-day a week.
- (2) Monthly meetings in the hospital for demonstration of cases and discussion.
- (3) Whole-time intensive general refresher courses once a year, lasting one week.
- (4) Short—perhaps week-end—courses on subjects in which progress of practical importance has recently been made—for example, treatment by penicillin, blood transfusion, etc.

These facilities for general practitioners would be arranged at hospitals other than those occupied with undergraduate teaching or with the training of specialists, but the staffs of teaching hospitals would take part. The experience gained with the courses for demobilized doctors should be of considerable value, especially in selecting suitable hospitals. It is proposed to begin arranging provisions on these lines as soon as there is a lessening of the demands for facilities for demobilized doctors, but some of them will probably not be practicable until the National Health Service is in being.

The British Postgraduate Medical School

The British Postgraduate Medical School (Ducane Road, Hammersmith) has been a school of the University of London since its beginning in 1935. Increasing demands for postgraduate education from the Dominions, Colonies, and foreign countries, sponsored by the Government or the British Council, have made it necessary to expand the clinical facilities at the school, and arrangements were made with the London and Middlesex County Councils for the accommodation of twenty additional graduate students in general medicine and twenty in general surgery from April of this year.

The teaching in the clinical departments consists of bedside teaching, reinforced with lectures, clinico-pathological conferences, radiological and post-mortem demonstrations, and attendance at operations. Clinical teaching is continuous, but organized teaching is arranged in sessions of about fourteen weeks, roughly from September to Christmas, January to April, and April to July. At present there are no vacancies until 1947. House appointments are usually made from among the students, and facilities are provided for senior students who wish to carry out original research under the director.

The department of medicine is organized in five clinical units, three at Hammersmith and two at auxiliary hospitals. About 90 students can be accommodated, and resident appointments are available for about 20. The department of surgery provides training for general surgeons, but instruction in orthopaedics, otolaryngology, and urology is included. Teaching is so organized as to be continued from out-patient departments through the wards and operating theatres to follow-up clinics. Students do not themselves perform operations. There are at present no facilities for work in preparation for the primary F.R.C.S. examination. In the department of obstetrics and gynaecology teaching is conducted in the ante-natal and post-natal clinics and in the sterility clinic as well as in the wards and operating theatres. The department of pathology is organized in four main sections: (1) morbid anatomy and histology, (2) bacteriology, (3) haematology and clinical pathology, and (4) biochemistry. The course lasts for a year and starts in October. There are at present only ten places available in the course. Fortnight courses in practical anaesthetics are also given. In the department of radiology teaching is based on the requirements for the diploma in medical radiology.

The Special Institutes

It remains to glance at the present position in the various institutes whose origin has just been described. The committee of management and academic board of the Institute of Child Health has been constituted. Dr. Alan Moncrieff began his duties as professor in January last, and two assistants have been appointed, one to work mainly at Great Ormond Street Hospital and the institute there and the other mainly at the British Postgraduate Medical School at Hammersmith Hospital in connexion with the department of obstetrics. Negotiations

with certain boroughs for their co-operation in respect of their maternity and child welfare clinics are taking place.

The Institute of Laryngology and Otology has received a grant as from January of this year. A lease of premises in Gray's Inn Road, close to the Royal National Throat, Nose and Ear Hospital, has been obtained. Mr. C. Gill-Carey has been appointed part-time dean, and the teaching is being developed by the staffs of the Royal National and Golden Square Hospitals.

The medical school at the Royal London Ophthalmic Hospital, Moorfields, has been reconstituted, with a separate committee of management and an academic board, as the Institute of Ophthalmology. It has come to an agreement with the Central London Ophthalmic Hospital, and the combined staffs are available for the purposes of the Institute. It is hoped that other ophthalmic hospitals in London will co-operate. Mr. R. C. Davenport has been appointed part-time dean, and arrangements for teaching and research are being planned. The appointment of professor in the year 1946-7 is under consideration.

As for the other institutes, the establishment of the Institute of Neurology is going forward in association with the National Hospital, Queen Square. It is considered that no action is required for the inclusion of Maudsley Hospital as it is already a school of the University, but its inclusion in due course as an Institute of Psychiatry is desirable. A financial grant is being made to the school through the Federation during 1946-7.

In addition to the various hospitals mentioned, arrangements have been made for clinical facilities at one L.C.C. hospital (St. James's) and at two Middlesex C.C. hospitals (Redhill County and North Middlesex) for postgraduate students of the departments of medicine and surgery at the British Postgraduate Medical School, and it is hoped to make similar arrangements with Queen Charlotte's and Chelsea Hospital for Women for the students of the department of obstetrics. It is possible that the West London Hospital may be associated on similar lines. Hospitals under consideration as associated hospitals of the Federation are Brompton, the Heart Hospital, St. Peter's, and the Royal National Orthopaedic.

As already stated, all the universities are making postgraduate arrangements of some kind, although, of course, on a very much smaller scale, except perhaps in Edinburgh. We have already alluded to the plans for postgraduate work which have begun to materialize at Cambridge. Glasgow is undertaking a large amount of postgraduate teaching, and it is intended to enlarge this field. At Liverpool postgraduate research students are being accommodated. Queen's University, Belfast, is developing plans for a postgraduate school. Up to now, in most of the universities, the postgraduate facilities have been concentrated on the administration of the Government scheme for postgraduate training of demobilized medical officers.

The Fellowship of Postgraduate Medicine, founded in 1919, as a bureau at 1, Wimpole Street, London, W.1, which affords general information on postgraduate work in London and elsewhere. It arranges classes at hospitals, also special courses of intensive study for those entering for higher examinations.

Special Courses

The Royal College of Surgeons is embarking on a programme of postgraduate teaching, including the study of the basic sciences. The College has a noteworthy list of lectures in anatomy, physiology, and pathology, and in surgery which will be given in the autumn months, and a similar series is planned for the early part of 1947. Some forty lectures in the first of these series are planned for September and October, including twelve by Prof. R. A. Willis on the study of tumours. These will be followed in October and November by twelve surgery lectures by well-known surgeons.

The impressive contribution to postgraduate knowledge afforded by the lectures at the Royal College of Physicians must not be overlooked in any assessment of facilities. The Croonian, Fitzpatrick, Oliver Sharpey, Milroy, Goulstonian, Lumleian, and other series, to which is now added the Humphry Davy Rolleston lectures, afford opportunities for the presentation of work in medicine such as could scarcely be forthcoming in any other way.

Courses in Public Health and Tropical Medicine

The London School of Hygiene and Tropical Medicine (Keppel Street, W.C.1) furnishes a course for the diploma in public health and for the diploma in tropical medicine and hygiene. During the next session there will also be a course for the academic postgraduate diploma in bacteriology, but there are now no vacancies for this course, and applications for the subsequent session should reach the school by March, 1947, as the number of places is strictly limited. The course for the D.P.H. is designed primarily for qualified medical practitioners who intend to enter the public health service in this country as medical officers of health. The course begins on October 1 and lasts one academic year of nine months. Examination for the certificate in public health is held at the end of three months. All the vacancies for the full course for the diploma have been filled and there is a waiting list. Applications for the course beginning in the autumn of 1947 will be considered early next year. In view of the development and subdivision of medical work in the public health service, some places in the course for the certificate in public health have been reserved for practitioners who intend to engage in public health work other than as medical officers of health.

The course at the London School for the diploma in tropical medicine (D.T.M.&H.Eng.) is designed primarily to prepare qualified medical practitioners for the examination of the Conjoint Board for this diploma. It is open to any qualified medical practitioner, but students not holding a qualification registrable in England should consult the secretary of the Conjoint Board (8, Queen Square, W.C.1) regarding their admissibility to the examination. Two courses will be given during the next session, the first starting on September 30 and the second on March 3. The examinations that conclude these courses will be held in March and July respectively.

The Incorporated Liverpool School of Tropical Medicine is now on a normal peacetime footing, though the staff is not yet up to full strength. The two separate diplomas in tropical medicine and tropical hygiene formerly offered were combined this year to form a single diploma in tropical medicine and hygiene (D.T.M.&H.). Courses of instruction for this diploma are given twice yearly, and each lasts about four months. During 1946-7 these courses will start at the beginning of September and January. They are open to postgraduate students only, of whom about 40 to 50 a term can be accommodated. Women students are accepted on the same terms as men. The address of the school is Pembroke Place, Liverpool.

Many of the university courses for diplomas in public health have been suspended, but some are resumed or on the point of resumption. At Leeds the D.P.H. course will be resumed next session. The Royal Institute of Public Health and Hygiene (28, Portland Place, W.1) arranges courses of lectures and laboratory instruction by qualified teaching staff for the diploma in public health. Students completing the course are entitled to enter for examinations for the D.P.H. of universities and medical corporations of the United Kingdom. Examinations for the certificate and diploma of the Institute are held twice yearly in London and at provincial centres in general and school hygiene and in child welfare.

Postgraduate Education in Psychiatry

The provisional National Council for Mental Health (39, Queen Anne Street, W.1) arranges training courses in child psychiatry and mental deficiency. Fellowships are arranged to enable qualified psychiatrists to obtain special training in child guidance at a recognized training clinic. Preliminary qualifications for award of fellowship are D.P.M. or equivalent experience in the psychoses, psychoneuroses, and mental defect. Fellowships are tenable, as vacancies occur, at the Child Guidance Training Centre, Woodside Hospital, Muswell Hill; the Tavistock Clinic; Maudsley Hospital; Hill End Hospital, St. Albans; and at the Child Guidance Clinics at Aberdeen, Birmingham, Bristol, and Manchester. Ideally the course lasts for 12 months' half-time attendance, but in special circumstances six months' full-time may be arranged. The course is recognized by the Ministry of Education as a

suitable qualification for the medical director of an Education Committee's Child Guidance Clinic, and it is at present the only course of training recognized specifically for this purpose, though it is possible to get equivalent experience by personal arrangement.

At present the provisional National Council arranges two courses a year for school medical officers in mental deficiency, backwardness, and maladjustment. They last for two weeks, but it is likely that as from March next they will be extended to three weeks. They include lectures and demonstrations in mental testing, clinical mental deficiency, child development, and child guidance. They include the duties of medical officers in ascertainment under the Education Act, 1944. The course is recognized by the Ministry of Education. The fee is five guineas. Local education authorities defray the expenses of school medical officers, but the course is open to any qualified medical man or woman.

The Council also runs from time to time short courses of lectures for doctors on various aspects of psychiatry and psychology.

Psychiatry

The Tavistock Clinic (the Institute of Medical Psychology) has lately entered its new home at 2, Beaumont Street, London, W.1, and is contemplating the full resumption of its pre-war activities. For many years it carried out systematized training for doctors in medical psychology. Before the war systematic courses of training were taken, lasting two years, by those wishing to specialize, in psychotherapy, and, lasting one year, by general practitioners who wanted to gain a knowledge of psycho-neurosis for use in their practice. This work was regularly carried on until the outbreak of war, and postgraduate students of the Clinic are now scattered widely throughout the British Empire and the Dominions. In addition to systematic training short lecture courses and week-end discussion groups were held for doctors, and a wide variety of educational activities for lay groups were undertaken.

The recent creation, with the aid of a Rockefeller grant, of an "Institute of Human Relations" at the Tavistock Clinic has entailed a revision and extension of training facilities. It is intended to offer, beginning in February, 1947, a four months' course in social methods to suitably qualified students, medical and non-medical, affording a basic training in diagnosis and treatment of social problems. It is also intended to offer seminars on certain selected psychological topics, to begin in February. Existing provisions for training suitably qualified physicians in individual adult psychotherapy will be continued, and the first post-war course, which begins in October, is being revised to bring it into line with the new developments.

The Institute of Psycho-Analysis (96, Gloucester Place, London, W.1) provides training in psycho-analytic theory and technique. The course is part-time and lasts about four years. It includes a personal analysis, attendance at lectures and seminars (held in the evenings), and clinical work done under supervision. Students are required to obtain general psychiatric experience at other clinics and hospitals; the Institute does not set out to teach all aspects of psychiatry. Completion of the course to the satisfaction of the training committee qualifies the student for election as an associate member of the British Psycho-Analytic Society. In addition to this main course designed for those intending to specialize, the Institute gives briefer courses from time to time on the application of the principles of psycho-analysis to medical problems. These are advertised in the medical press.

POSTGRADUATE COURSES FOR INSURANCE PRACTITIONERS

Reintroduction Contemplated by Ministry of Health

It was reported to the meeting of the Insurance Acts Committee on Sept. 5 that the Ministry of Health was contemplating the reintroduction of postgraduate courses for insurance practitioners, pending the provision of such facilities under the National Health Service. It will be recalled that such courses were arranged in London and other centres until the outbreak of war caused them to be suspended. The new proposal is

dependent on the willingness of the universities to continue during 1947 the courses of postgraduate instruction for demobilized doctors, the demand for which will shortly decline. Ex-Service medical officers who wish to do so will be able to avail themselves of the courses, the arrangements being similar to those at present in operation under which the fees and subsistence expenses will be defrayed from Treasury funds.

The courses contemplated may be of several types, such as a two weeks' intensive course of 22 sessions in general medicine or in some approved specialized subject, a one week's intensive course of 11 sessions, again in general medicine or a specialized subject, or an extended course, such as two afternoons a week for eleven weeks. The syllabus will be subject to the general approval of the Minister. During 1947 a doctor will be allowed to take one two-weeks course or two one-week courses. To be eligible for financial assistance for meeting expenses, which will be paid from National Health Insurance Funds, an insurance practitioner must have at least 300 insured persons on his list if his practice is an urban one, or 150 persons if it is rural; at least three years must have elapsed since his qualification, and he must not have attended any of the courses for demobilized officers. Expenses will be paid as follows: course fee, 7½ gns. for a two-weeks course or 4 gns. for a one-week course; subsistence allowance up to £1 a day, if attendance necessarily entails absence from home at night, or otherwise actual expenses up to 5s. a day, and travelling expenses at third-class monthly return rates. The expenses of providing a locum tenet, where necessary, up to 12 gns. a week will also be met. Originally the Ministry suggested 10 gns. a week for a locum tenet, but later, on representations being made to them by representatives of the Insurance Acts Committee, agreed to raise the fee to 12 gns.

Under these arrangements, which will be without prejudice to future arrangements under the National Health Service proposals, an insurance practitioner will be given freedom of choice of the centres where courses are available. It is understood that the Ministry proposes to send a circular on the subject to every Insurance Committee, with copies to Panel Committees for their information.

When the provisional proposals came before the Insurance Acts Committee they were generally approved subject to certain qualifications. It was pointed out that 12 gns. was below the customary cost of a locum tenet; this cost as a general rule was at least 14 gns., and a Lancashire representative said that it was from 15 gns. to 20 gns. in the north-west. It was agreed to press for an upwards revision of this allowance to 14 gns., and also that first-class fares of the practitioner should be paid. It was further agreed to urge on the Ministry of Health that the 300 and 150 minimum of insured persons on the practitioner's list should not be rigidly adhered to as governing eligibility for the course, and it was pointed out that there might be a partnership in which the insured persons were entered on the list of one partner, but were attended equally by the other. The need for a certain amount of flexibility in this arrangement was expressed.

THE PUBLIC SERVICES

The majority of men and women after qualification and the filling of one or more resident appointments in hospital become general practitioners, usually starting as assistants and presently entering independent or partnership practice. Some, after a course of postgraduate study and obtaining the appropriate degrees or diplomas, become specialists or enter a branch of the public service. Laboratory work and medical research also offer interesting, though not highly paid, opportunities.

In the public health service a wide range of openings is now afforded in the shape of appointments under local authorities; there are also a number of posts of medical officers in Government departments. The senior posts in the public health service are now almost entirely administrative; junior posts may also be administrative, though more frequently they are mainly clinical, perhaps with some administrative responsibility. The effect of National Health Service legislation on the public health service cannot yet be fully estimated, but it seems likely that there will be an increased field for clinical preventive work.

New rules were promulgated by the General Medical Council to operate from Jan. 1, 1946, aiming at a more rational method of training for work in public health departments under modern conditions. The nature of the preliminary and final examinations has been indicated in the section headed "Postgraduate Education."

What was known as the Askwith agreement for many years determined the scales of remuneration in public health appointments, hospital and other, under local authorities. This agreement was terminated on March 31 of this year, and an interim agreement, without prejudice to an eventual settlement when conditions have become more stable, has been arrived at at a conference of the various associations of local authorities with the British Medical Association. Certain percentage increases on the basic "Askwith" rates hitherto in force have been accepted, benefiting more particularly those whose minimum is below £1,000. The new scales were set out in the *Supplement* of July 13 (p. 8).

The largest employer of public health medical officers is the London County Council, with its 76 general and special hospitals and its 21 mental hospitals and institutions for mental defectives. A proposal which the Council is pursuing is to divide London into some twenty districts, each to be served by a general hospital dealing with acute cases, with other hospitals related to it and supplying a complete medical service. In about half these districts the main hospital would be the council hospital and in the others a voluntary teaching hospital. Special units for certain types of medical and surgical treatment would be situated at suitable hospitals. Most of the general hospitals are already recognized training centres for candidates for the University of London M.D. examination, and a number of them for the diploma of Membership of the Royal College of Obstetricians and Gynaecologists and for the final F.R.C.S.

Apart from the London county mental hospitals there are 91 mental hospitals in England and Wales and 23 in Scotland under the control of local authorities, and some 20 in the whole of Great Britain administered by voluntary bodies. Assistant medical officers in mental hospitals are paid in accordance with the scales laid down in the former Askwith agreement, and to these the new interim scales will apply. Mental hospital medical superintendents and their deputies, however, together with some mental specialists, have been outside the agreement, and it is being represented that the new proposals should apply to them also.

Before the war there were about 50 whole-time and part-time medical officers in factories. During the war, owing to the Factories (Medical and Welfare Services) Order, 1940, which may require the owner of a factory at which any Government work is done to appoint doctors, nurses, and welfare supervisors, there was perhaps a twenty-fold increase in the number of industrial medical officers, and it is expected that many of these posts will become permanent. A very large proportion of factory workers, however, work in places too small to employ a whole-time medical officer. Something is being done in the way of grouping small factories for this purpose, and also in the employment of part-time factory doctors. The Association of Industrial Medical Officers (London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1) looks after the interests of these officers, and the British Medical Association publishes the *British Journal of Industrial Medicine*.

H.M. Forces offer openings for medical officers. Before the war candidates, who were normally required to be under 28 years of age, were accepted on a short service commission basis for a period of three to five years. At the end of their short service period they had an option of being considered for a permanent commission or of retiring with gratuity. The scheme for short service commissions is at present suspended, and all applications are dealt with by the Central Medical War Committee at B.M.A. House, London, or in Scotland by the Scottish Central Medical War Committee at 7, Drumsheugh Gardens, Edinburgh, 3.

The method of recruitment to the Indian Medical Service was altered during the war, and those wishing to be appointed are required first to join the R.A.M.C. After a course of instruction they are able to be posted to the Indian establishment and are then given the opportunity to transfer to the I.M.S. Full information regarding appointments may be obtained from the

Secretary, Military Department, India Office, Central Buildings, Matthew Parker Street, S.W.1.

The Colonial Medical Service offers many posts for men and women doctors. A candidate's preference for any particular colony is given full consideration, though it may not always be possible to meet his wishes. Vacancies occur most often in the larger medical departments in tropical Africa. Generally speaking, the initial salary is from £600 to £700 on a scale rising to £1,000 or £1,120 per annum, but there are a number of higher scale posts, both administrative and specialist, with salaries up to £2,000. Government quarters are provided, together with first-class passage to and from the territory. Officers in this Service have special opportunities in preventive medicine. Inquiries should be addressed to the Director of Recruitment, Colonial Office, 15, Victoria Street, London, S.W.1. A Colonial Medical Research Service is being formed.

Those who wish to put into the hands of a young man or woman a succinct and authoritative statement of the qualifications, training, and prospects of employment will find it in a threepenny booklet prepared by the Ministry of Labour and National Service, in the "Careers for Men and Women" series, No. 32, *Medicine and Surgery*. It is obtainable at H.M. Stationery Office.

HIGHER QUALIFICATIONS

Diploma in Public Health

The Diploma in Public Health, granted jointly by the two Royal Colleges (D.P.H., R.C.P.Lond. and R.C.S.Eng.) is open, after a stipulated interval, to those who have passed a recognized final qualifying examination in medicine, surgery, and midwifery. For admissibility to the preliminary examination the curriculum of study must extend over one academic year whole-time or not less than eighteen calendar months part-time. Both the preliminary and final examinations are normally conducted twice yearly—in June and December—and candidates must give notice to the Secretary of the Examining Board in England, Examination Hall, Queen Square, London, W.C.1, twenty-one days before the examination begins, and must furnish the necessary certificates.

The preliminary course consists of systematic instruction in the history of public health and public assistance, the functions of central and local authorities, social security, the statistical presentation of public health data, the causal agents of infection and their control, the influence on health of heredity and of environment, physical education, and the principles of education. The course must include practical demonstrations, exercises in epidemiological problems, and visits to places and institutions of importance to public health. The examination consists of two written papers and an oral session.

Those who pass this examination receive the "Certificate in Public Health" of the R.C.P.Lond. and R.C.S.Eng., and the possession of this certificate makes them eligible to begin the course of study required for admission to the final examination. The final course includes systematic instruction in a large number of subjects such as physiology, biochemistry, food, and nutrition in relation to public health; bacteriology, parasitology, and medical entomology, as applied to epidemiology; mass aspects of disease; sanitation; statistical methods and data; the law relating to public health; mental health services; and occupational health. Candidates are required to produce a certificate of having resided and received instruction for four weeks in an infectious diseases hospital or of having regularly attended at such a hospital for three months, also of having for not less than five months attended the health department of a local authority and personally studied the daily work of each section of such department under proper guidance. The examination consists of three written papers, a clinical examination in infectious diseases, an oral examination in that subject and in epidemiology and general and special hospital administration, and a general oral examination. The whole examination must be passed at one time. Candidates who pass the examination are then granted the diploma.

D.P.H. courses are being resumed at the Universities of Liverpool, Leeds, the Welsh National School of Medicine, and a number of others after suspension during the war.

A Simple and Accurate Tuberculin Skin Test

The application of Tuberculin Diagnostic Jelly A&H to the skin is a convenient and reliable means of detecting positive reactors to old tuberculin. In controlled observations, the results have been as reliable as those obtained with the intracutaneous technique of Mantoux.

The test does not involve the discomfort of injection; it is easily and rapidly carried out; the area of positive reaction is sharply circumscribed: there is no untoward local or constitutional reaction, and no risk of infection.

(See reports, *Brit. med. J.* (1944) i. 531—*Med. Off.* (1945) lxxiv, 209—*Lancet* (1946) i. 162.)

It is available in tubes of 2 gm. (20 tests) and 5 gm. (50 tests).

Therapeutic Substances Act, Licence No. 6a.

DIAGNOSTIC JELLY A&H**

ALLEN & HANBURY LTD. LONDON, E. 2

To be sure . . .

Specialisation in sutures over the last sixty years has given Johnson & Johnson a leadership which is literally world-wide. Take, for example, their Ethicon Non-Boilable Catgut Sutures. These, as taken from the sterile tubes, have more tensile strength than is required to ligate the largest human blood vessel or to suture the most dense human tissue. It is interesting to record that Johnson & Johnson are Sole Agents for the new biologically inert Surgical Metal—Tantalum. Ethicon Tantalum Sutures are likely to play an important part in surgery of the immediate future.

'BEPLEX' BRAND CAPSULES

are indicated for patients with increased nutritional needs during convalescence, pregnancy and lactation, the growth period, and senility.

'Beplex' capsules provide natural vitamin B complex plus added B₁ and B₂.

Of the B-vitamins known to be essential in human nutrition, 3 'Beplex' capsules provide the following quantities:

Thiamine Hydrochloride 10'0y;
Riboflavin 800y; Nicotinic Acid
(Niacin) 5000y; Pyridoxin
12y; Pantothenic Acid 13y

Supplied in bottles of 50 Capsules.

Vitamins in diseases of the nervous system

Condition	Indications	Therapeutic Agents
PERIPHERAL NEURITIS occurring in:— pregnancy diabetes alcoholism.	May indicate that the increased demand for vitamin B ₁ is not being met.	VITAMIN B₁ (Aneurin hydrochloride) Vitamins Ltd.: 10 mg. or more daily by mouth or hypodermically.
SCIATICA and FACIAL NEURALGIA	In the absence of pathological or structural lesions of a focal nature, high doses of vitamin B ₁ may prove beneficial.	VITAMIN B₁ (Aneurin hydrochloride) Vitamins Ltd.: 10 to 100 mg. daily by mouth or by injection. Massive doses should be accompanied by either BEFORTISS B complex capsules or BEMAX to supply the other factors of the B complex.
HERPES ZOSTER and frontalis	The pain of these conditions is lessened and the duration reduced by the addition of vitamin B ₁ to other forms of treatment.	VITAMIN B₁ (Aneurin hydrochloride) Vitamins Ltd.: 10 to 100 mg. daily by mouth or by injection.
MÉNIÈRE'S SYNDROME	Relief has been obtained from combined therapy with vitamin B ₁ and nicotinic acid.	VITAMIN B₁ (Aneurin hydrochloride) Vitamins Ltd.: Tablets 3 mg.—one thrice daily. NICOTINIC ACID Vitamins Ltd.: Tablets 50 mg.—once daily.
DEPRESSIVE PSYCHOSES	These states may be associated with a need for nicotinic acid.	NICOTINIC ACID OR AMIDE , Vitamins Ltd.: 50 mg. once or twice daily.

Further particulars of the various vitamin products are obtainable on request from

Diploma in Industrial Health

The first examination for the Diploma in Industrial Health (J.I.H., R.C.P.Lond. and R.C.S.Eng.) will be conducted in December, 1946, Part I beginning on Dec. 13 and Part II on Dec. 27. Candidates are admissible to Part I 24 months after having passed a qualifying examination in medicine, surgery, and midwifery. The candidate is required to produce a certificate of regular attendance at a course extending over one academic term of not less than ten weeks of whole-time study or an equivalent period extending over not less than five months of part-time study, covering in either case not less than 300 hours. The systematic and practical instruction required is the same as for Part I of the examination for the D.P.H.

For Part II the candidate is required to have attended regularly at a recognized institution subsequent to having passed Part I, a course extending over not less than five calendar months of whole-time study or an equivalent period extending over not less than twelve calendar months of part-time study, covering in either case not less than 550 hours. Systematic instruction is required in the structure of industry and industrial relations, the development of industrial health and legislation relating thereto, the organization of a health service in industry, applied physiology in industry including mines, industrial psychology, placement of workers, industrial accidents and occupational diseases, rehabilitation and resettlement in industry, and special problems relating to employment of women and young persons. The practical instruction must include visits to industrial establishments, docks, shipyards, and mines, attendance at a skin and an ophthalmic clinic for 12 and for 6 sessions respectively, attendance at an accident department of a hospital for 12 sessions, six visits to recognized rehabilitation and retraining centres, and attendance at various works' surgeries and works under the instruction and supervision of industrial medical officers.

Each part of the examination consists of two written papers of three hours each and an oral examination, and for Part II a clinical examination also is required. Further particulars can be obtained from the Secretary of the Examining Board, Queen Square, London, W.C.1.

The Society of Apothecaries of London (Apothecaries Hall, Blackfriars Lane, E.C.4) has instituted an examination for the diploma in industrial health, embracing the history and legislation relating to industrial health, occupational diseases, the industrial environment, the practice of industrial medicine, and clinical medicine and surgery as applied to industry. The examinations are held in February, May, August, and November.

Other Special Degrees and Diplomas

The Examining Board in England (English "Conjoint") offers diplomas in laryngology and otology, ophthalmic medicine and surgery, anaesthetics, child health, physical medicine, medical radiotherapy, medical radio-diagnosis, psychological medicine, and tropical medicine and hygiene.

The Society of Apothecaries of London grants the Mastery of Midwifery (M.M.S.A.) upon examination in obstetrics, paediatrics, and public health. The examinations are held in May and November. The Royal College of Obstetricians and Gynaecologists grants a diploma to practitioners who have had special postgraduate experience in obstetrics.

Several of the universities normally offer diplomas in psychological medicine, but in some of them the course is still suspended. A D.P.M. course is normally held at Maudsley Hospital (L.C.C.) in the early months of the year.

The Faculty of Radiologists (Warden, care of Royal College of Surgeons, Lincoln's Inn Fields, W.C.2) grants a Fellowship to medical graduates of five years' standing who have spent at least one year in general clinical work at an approved hospital, have practised radiology exclusively for three years, and have held a radiological diploma for at least two years. The Universities of London and Edinburgh grant diplomas in medical radiology.

The University of Oxford grants a diploma in ophthalmology. University College, Dublin, offers a diploma in child health. Diplomas in bacteriology are ordinarily granted by the Universities of London and Manchester; the University of London offers a diploma in clinical pathology, and Liverpool University the

degree of Master of Surgical Orthopaedics. The Irish Conjoint Board issues diplomas in ophthalmology, anaesthetics, child health, and psychological medicine.

The Royal College of Surgeons of England is making application for a supplemental charter to enable (1) the F.R.C.S. to be obtained by ophthalmological candidates who pass the normal primary examination and a special final examination equal in standard and similar in form to the ordinary examination, and (2) to have power to grant a higher dental diploma entitled the "Fellowship in Dental Surgery."

TUITION AND EXAMINATION FEES

The fees charged at medical schools vary to a considerable extent as between one school and another, but the estimated average cost of training over six years, including books and instruments, is placed at between £320 and £360. To take a typical school—Charing Cross—£340 is mentioned as the total cost to qualification, provided the course is continuous and the examinations are passed at the normal times. This estimate covers the first M.B. in the case of degree students and the pre-medical examination in the case of students reading for the Conjoint diploma. The entrance fee is 10 gns., the tuition fees for the first M.B. are £40 per annum and for the second M.B. £44 per annum, and for the clinical courses there is a composition fee of 38 gns. The composition fee does not include the fee for the course in fevers and infectious diseases (3 gns.), the fee of 1½ gns. paid to the public vaccinator, and the sum of £5 per month which midwifery clerks, during their residence in hospital, are required to pay towards the cost of their board.

The examination fees for the University of London M.B., B.S. total 33 gns., and for the Conjoint Board 46 gns. The latter fee is made up of 6 gns. for the pre-medical examination, 8 gns. for Part I of the first examination and 2 gns. for Part II, and, for the final examination, 4 gns. for Part I, 10 gns. each for Parts II and III, and 6 gns. for Part IV. For admission to re-examination the fees are reduced, the fee for the final examination being 20 gns., as compared with 30 gns., for the first admission. The examination fee for the L.R.C.P., L.R.C.S. Ed., L.R.F.P.S. Glas. is £33, and the licentiate fee L.M.S.S.A. 25 gns. The fees for university degree examinations vary between £20 and £40. The qualifying degrees of the universities are the following: the B.M., B.Ch. of Oxford, the M.B., B.Chir. of Cambridge, the M.B., B.S. of Durham and London, the M.B., Ch.B. of the Victoria University of Manchester and of the universities of Birmingham, Liverpool, Leeds, Sheffield, Bristol, Edinburgh, Aberdeen, Glasgow, and St. Andrews, and the M.B., B.Ch. of Wales, Queen's University of Belfast, Dublin, and the National University of Ireland.

To the fees for tuition and examination given above the cost of maintenance must of course be added. Some investigations made at Newcastle recently showed that the total cost of six years' studentship worked out at £1,070 if the student lived at home and £1,380 if he was in lodgings; but there is a great difference in these costs as between London and the provinces, and between the provinces and Scotland. At Oxford the cost, in 1945, of the residential part of the course was about £250 per annum; this has risen slightly since that time as tuition fees have been increased.

Further fees for tuition and examination will of course be required if it is decided to proceed to higher degrees or diplomas. The fee to be paid before examination for Membership of the Royal College of Physicians of London is 10 gns., but this is reckoned as part of the fee for admission as a Member in the event of the candidate satisfying the censors' board of his competence. Before admission as a Member the fee to be paid is 40 gns., except when the candidate for Membership is already a licentiate of the College, when the fee already paid for the licence (15 gns.) is deducted from the larger amount. For the Fellowship of the Royal College of Surgeons the fee payable for admission to the primary examination is 8 gns. and to the final 15 gns., and the fees payable before the diploma can be granted, in addition to the fees for admission to the examinations, are 10 gns. for members of the College and 30 gns. for all other candidates. The fee paid by the candidate for the Membership examination of the Royal College of Physicians of Edinburgh is 35 gns., and when the Member is

raised to the rank of Fellow he is required to pay 38 gns., exclusive of stamp duty. The stamp duty on the Fellowship, payable to the Government, is £25.

The fee for admission to the examination for the D.P.H. by the Examining Board in England (the "Conjoint") is 6 gns. for the preliminary examination and 6 gns. for the final, and there is a diploma fee of 5 gns. The fee for admission for the D.T.M.&H. is 10 gns. At the Liverpool School of Tropical Medicine the fees for the course of instruction for the diploma are 30 gns., and for the revision course 22½ gns. For admission to the university examination the fee is 6 gns. and the fee for the diploma 3 gns. At the London School of Hygiene and Tropical Medicine the tuition fee is £40 for the D.T.M.&H., and £56 14s. for the D.P.H.

The young student should inquire concerning the numerous public secondary school scholarships and State scholarships which are available from school to university. A number of scholarships, exhibitions, and prizes are awarded directly by medical schools. The combined hospital university entrance scholarships are awarded every year to second and third-year students who have passed the intermediate examination in anatomy and physiology of a British university outside the London area. The arrangement covers three schools—St. Bartholomew's, Guy's, and St. Thomas's. The Royal College of Surgeons awards the Macloghlin scholarships to young men seeking to qualify themselves as members of the Royal College and who need financial assistance for the prosecution of their studies. The examination is competitive; and no scholarship is awarded to any candidate who does not obtain pass marks in all three subjects of the pre-medical examination—chemistry, physics, and biology. The scholarship may be tenable for five years and is of the value of £90 a year. Another prize of the Royal College is the Begley prize awarded to the candidate obtaining the highest number of marks in anatomy and physiology combined.

ON QUALIFICATION

At innumerable gatherings of final-year students and the newly qualified the advice is given to do two things on qualification: (1) to join the British Medical Association, and (2) to join a defence society.

The British Medical Association

The British Medical Association, with which the Canadian Medical Association is affiliated and the Medical Association of South Africa is shortly to be affiliated, has a membership of over 52,500. Medical practitioners are elected to membership by the Council of the Branch in the area in which they reside, or, if not resident within the area of a Branch (e.g., serving with H.M. Forces), by the Council of the Association. The ordinary subscription for members resident in Great Britain and Northern Ireland is 3 gns., but there are remissions of part of the subscription in certain cases and newly qualified practitioners admitted to membership within the first two years of their registration pay only 1½ gns. until the end of their fourth year. For members not resident in Great Britain and Northern Ireland the subscription is ordinarily 1½ gns., and for medical officers serving with the Forces (apart from the above concession to newly qualified practitioners) the subscription is 2 gns. Forms of application are obtainable from the Hon. Secretary of the Division or Branch or from the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The privileges of a member include participation in all the activities of the Association, local and central, the receipt weekly of the *British Medical Journal* and its *Supplement*, participation in the government of the Association and in the formulation of its policy, the use of the houses of the Association, with, at the London house, library and common room, and the advice and help of the central staff in professional matters. The Scottish House of the Association is at 7, Drumsheugh Gardens, Edinburgh, 3.

The Defence Societies

The London and Counties Medical Protection Society (Victory House, Leicester Square, W.C.2) has a membership of 22,000 and financial resources amounting to £143,000. During 1945 it received over 1,000 applications for advice and assistance. Practitioners

returning to civil life on release from the Forces have found it very advantageous to consult the Society.

The Medical Defence Union, which has recently celebrated its diamond jubilee, has 29,800 members, and has also undertaken much useful medico-legal work on behalf of its members. The cases which come into court are, of course, only a small fraction of those with which a defence organization is daily called upon to deal.

In Scotland the Medical and Dental Defence Union (113, St. Vincent's Street, Glasgow, C.2) has a membership of between 4,000 and 5,000. A standing joint committee with representatives of all three societies has been set up. It is an advisory body and recommends to the respective councils lines of action to be followed in appropriate cases.

BRITISH MEDICAL STUDENTS ASSOCIATION

The British Medical Students Association was established a few years ago with the active encouragement of the British Medical Association, which continues to afford it secretarial assistance and hospitality at B.M.A. House. It is the only body through which the medical students of this country can speak with a united voice on the subject of their future. Nearly all the British medical schools are members of the Association. Irish medical students have their own Association, but this is linked with the B.M.S.A., and observers from Irish schools attend its annual congresses. Some highly successful congresses have been held in London and have been addressed by Ministers of Health and others. The B.M.S.A. has been fortunate in its able leaders, though it is unfortunate in the fact that attainment of qualification so quickly sweeps them out of undergraduate life. On the other hand, there is no bashfulness on the part of first-year men, and there is a refreshing spirit of criticism among the rank and file.

The B.M.S.A. has endeavoured to elicit the opinion of students on many issues appertaining both to undergraduate and qualified status. One representative of the Students Association—a woman—serves on the B.M.A. Curriculum Committee now sitting. At no time has the Students Association gone deeply into the details of the curriculum, though quite a number of student bodies at the individual schools have done so. The Government's Health Service Bill has been the subject of a questionnaire with a view to collecting and summarizing student opinion on the subject. Schools have been asked to arrange meetings for discussion of the Government proposals and regional meetings have also been called. It should perhaps be stated that the B.M.S.A. keeps itself quite clear from any form of party political activity.

The Cost of Medical Education

The B.M.S.A. is collecting material on the cost of medical education and the extent to which financial help is available by means of scholarships, grants, or loans. Recent increases in student fees, especially at Oxford, have drawn attention to the fact that many colleges, in order to meet increased costs, are obliged to seek an increased income. The National Union of Students committee at Oxford has drawn up a detailed statement of the position, and on the basis of its conclusions the Union has formulated a three-point policy: (1) that where universities or colleges cannot meet increased costs the resultant deficit in their budgets should be made up by direct Treasury grants to the University concerned through the University Grants Committee, and not by an increase in the fees charged to students; (2) that there is a need for an increase in the number and amount of grants to students, but that such increases should be made in order to supplement the net income of the student and not merely to enable him to pay increased fees; (3) that in the case of Oxford University, where colleges have already increased fees or have announced increases, and of any other university where similar increases are foreshadowed, increased grants should be made and fees for students restored to at least the 1939 figure. The B.M.S.A. has sought the opinion of its members on this policy.

One important piece of work has been in connexion with medical films, and the B.M.S.A., in the absence of a more ambitious work of the kind, prepared a film catalogue. A questionnaire on the subject of medical films has been circulated. Many branches of the B.M.S.A. have appointed a film secretary, and have pressed their schools for the more general use of teaching films and sound projectors. The question of student health has occupied a good deal of attention, together with the parallel question of nutrition. College canteens are frequently only in the "C" category for the supply of rationed foods, and, in London schools particularly, the provision of the midday meal for students is a serious problem.

Much thought has been given to the question of student exchange as between home and foreign universities, and also as between medical schools and hospitals in this country. Student-staff committees have also been formed, enabling the students to put forward their views and proposals to the governing bodies. Finally, the B.M.S.A. has produced a journal, the first ordinary issue of which appears in the autumn.

THE INSURANCE CAPITATION FEE FAILURE TO APPLY SPENS REPORT PANEL CONFERENCE TO BE RECOMMENDED TO CALL FOR RESIGNATIONS

the following recommendation, which has been sent to all Panel Committees with a view to its endorsement for submission to the Panel Conference to be held in London on Oct. 24, was passed unanimously at a meeting of the Insurance Acts Committee (Dr. E. A. Gregg presiding) on Sept. 5:

That in view of the Minister's failure properly to apply the report of the Spens Committee to the current capitation fee—despite explicit government promises that this would be done—and in view of the inadequacy of 12s. 6d. as remuneration for assuming medical responsibility for an insured person for a year, it is recommended that all insurance practitioners in England and Wales, Scotland, and Northern Ireland to place their resignations from the National Health Insurance Service in the hands of the Insurance Acts Committee, and to authorize that Committee, at its discretion, to put in their resignations to Insurance Committees unless the Minister is willing fully to apply the Spens Report to the current capitation fee, with effect at least from Jan. 1, 1946, or, failing agreement, to refer to the Spens Committee or a representative section of that Committee, or other agreed independent body, the question of the interpretation of the Spens Committee Report in relation to the current capitation fee, both parties agreeing in advance to accept the findings.

The adoption of this recommendation came at the end of a three hours' discussion on the impasse created by the refusal of the Ministry of Health to give full effect to the findings of the Spens Report in so far as the present remuneration of insurance practitioners is concerned. At the previous meeting of the Insurance Acts Committee, reported in the *Supplement* of July 27 (p. 32), the earlier stages of this controversy were fully set out. At that meeting it was announced that the Minister had offered a two shillings' increase in the capitation fee, making it 12s. 6d., with retrospective effect to Jan. 1, 1946. The Spens Committee found that the remuneration of doctors general in 1939 was up to £200 (on average £170) below what should have been, and the contention of the Insurance Acts Committee was that this deficiency should be considered wholly or almost wholly in relation to the part of income derived from insurance practice, because in relation to his private fees the doctor was in a position of control, whereas his insurance income was based on a rate which he could not adjust. Taking the pre-war capitation fee of 9s., which was generally considered to be much too low, this addition would have brought it up to pre-war standards, to between 12s. and 13s., and if to this betterment factor of 22% was added to meet the change in values since 1939, it indicated a capitation fee of about 15s. The Committee, therefore, while welcoming the Minister's acceptance of the Spens Report, considered the proposed increase to 12s. 6d. as "gravely inadequate," and suggested that the Minister was unwilling to make the interim fee 15s. the Spens Committee itself should be asked to state the implications of its findings in relation specifically to the current remuneration of insurance practitioners.

The reply of the Minister was now reported. In the Minister's view it was impossible to consider separately the remuneration of insurance practitioners at present and the remuneration of general practitioners in the future National Health Service. Unless the two were discussed together he saw no useful purpose in a further meeting with the Insurance Acts Committee. In July 30 a further letter was sent to the Ministry giving chapter and verse for the claim that one of the objects in establishing the Spens Committee was to give effect to the undertaking of the then Minister (Mr. Ernest Brown) to have the object of insurance practitioners' remuneration approached new, in Mr. Brown's phrase, "from the ground up."

Your letter (the reply of the I.A.C. continued) goes on to repeat the argument that it is impossible to consider separately the question of future remuneration under a Bill which is not yet law, and that of the remuneration of insurance practitioners to-day. The Committee cannot accept this view. On a number of occasions it has been made plain to the Minister and his officers that the representatives of the profession have, as yet, no authority to discuss the mode and amount of remuneration in any new service which may be established. . . . The Committee is quite unable to appreciate

why the Minister maintains that the question of remuneration in the new service and that of the current capitation fee must necessarily be considered together."

The correspondence was closed with a further letter from the Ministry stating that the Minister felt that the probability that the new health service would be in operation in the reasonably near future produced a situation in which it was obviously right to consider the whole question of present and future remuneration as a single issue now, in the light of the Spens Report, and that all the Minister could do in the circumstances was to give effect to his undertaking to increase the existing capitation fee to 12s. 6d., retrospectively to Jan. 1, 1946, and this was done by a circular letter to Insurance Committees on Aug. 19.

A Critical Issue

In opening the debate in the Insurance Acts Committee on Sept. 5 Dr. R. W. COCKSHUTT said that this was a critical issue. Insurance practitioners would be right to take their stand on the principle that they wished their remuneration to be settled by the tribunal—the Spens Committee—to the setting up of which both sides had consented. If there was any doubt as to the relation of the findings of the Spens Committee to insurance remuneration it was the Spens Committee itself which should be asked to resolve it. He hoped that the necessary steps would be taken forthwith to obtain from the insurance practitioners of the country the necessary three months' notice to terminate their agreements. Here for the first time in its dealings with the Minister the profession had the opportunity of taking the initiative; hitherto the Minister had had it all in his own hands.

Dr. GREGG from the Chair reminded the Committee of the previous occasion when a similar conflict arose. This was in 1923 when the Minister of Health, the late Lord Brentford (then Sir William Joynson-Hicks), made an offer of a capitation fee of 8s. 6d. for three years or 8s. for five years. This offer was rejected by the Insurance Acts Committee of the time, and a request was made for arbitration, which was refused. The resignations of insurance practitioners were called for, and these were forthcoming in the extraordinary proportion of 95%. An arbitration court was then set up, before which the late Sir Henry Brackenbury presented the case with the skill of a trained advocate, and the award of the court was 9s.

Dr. J. A. PRIDHAM said that on this question the profession had been treated with contempt. It had been promised an investigation "from the ground up," the proposal to set up the Spens Committee was first announced by the Ministry to the Insurance Acts Committee, the Spens Committee was the obvious fulfilment of the promise given, the present Minister continued that Committee when he came into office, he had accepted its findings, but he now refused to apply them unless the profession consented to negotiate with him on something which had nothing to do with the present issue at all.

Remarks of similar tenor were made by Dr. W. D. STEEL, Dr. J. C. PEARCE, Dr. W. V. HOWELLS, Dr. KATE HARROWER, and other members.

The CHAIRMAN OF COUNCIL (Dr. Dain), who was asked for his view, said that he was in entire accord with these expressions. He agreed that this question would have an enormous effect on the voting in the forthcoming plebiscite, but he reminded the Committee of one point which it was necessary to bear in mind in dealing with their "weaker brethren" in the constituencies—namely, that insurance practitioners would receive with their next quarterly cheques an addition to the usual amount, and in the eyes of some this might obscure the principle involved. It was necessary to state quite definitely that such an addition must not be interpreted as an acceptance by the profession of the Ministry's view that 12s. 6d. was the appropriate fee. With regard to the previous arbitration the circumstances of which had been recalled, he thought that this time there would be less difficulty in collecting an overwhelming number of resignations than there was in 1923, because at that time there was some indecision and divided counsel among the leaders, nothing of which now obtained.

A Unanimous Conclusion

Dr. A. BEAUCHAMP said that the Minister had not made out any case for tying up the remuneration under the future

National Health Service and the current capitation fee. The nexus was simply in the Minister's own mind.

Dr. S. WAND agreed that this was the proper time and the proper ground for a trial of strength with the Ministry, but he wondered whether it was the right course to suggest any further resort to arbitration. To his mind the arbitration had already taken place, and the result had appeared in the report of the Spens Committee. The profession had been let down by the refusal of the Minister to give effect to that report. Dr. HOWIE WOOD expressed the same view. He considered that it would be a great mistake to ask for further arbitration. Similar views, questioning the necessity for any further arbitration, were put forward by Dr. A. CAMPBELL, Dr. LEWIS LILLEY, Dr. J. A. IRELAND, and other members.

The CHAIRMAN invited every member of the Committee to express his views and, as far as he could, the opinion prevailing in his locality, and every member did so.

Dr. J. A. BROWN (Chairman of the Panel Conference) said that it seemed clear that there had to be a fight with the Minister at some time or other, and it seemed to him that the present was the time. If this were allowed to slip by and the fight reserved for the wider issue on the working of the new Act so many other considerations would come in and so many controversial facets would be presented that they might lend themselves to the accusation of trying to fight on one issue in order to secure a decision on another. It was much better to fight now on the simple issue presented. Dr. C. F. R. KILLICK, speaking for the West Country, said that he was sure that if a stand were taken on this issue it would be of enormous advantage in the further struggle ahead. Dr. TALBOT ROGERS said that in Kent they spoke with one mind on this subject. Their only criticism was that the sum of 15s. should have been mentioned in the earlier resolution; in their view the amount should have been larger. Dr. F. M. ROSE said that he was in full agreement with all that had been said, but he thought from some knowledge of Lancashire that a good deal of staff work would be needed if those practitioners who medico-politically were apathetic were to be seized of the situation. Dr. S. A. FORBES said that in his part of Surrey he was confident that there would be full support for the policy of handing in resignations. Dr. F. GRAY, in speaking in full support of the action proposed, said that he thought some members were laying too much stress on the political complexion of the present Minister and too little on the habit and tradition of the department. This sort of thing had been part and parcel of the policy of the Ministry for many years before the advent of the present Government. Dr. D. J. B. WILSON said that he had no doubt about the response in his own county of Buckinghamshire, but there might well be a certain "tail" of practitioners who were imperfectly acquainted with the situation, and some canvassing would be necessary.

The Scottish representatives spoke in full support of the policy of the Committee, as did representatives from Yorkshire, Merseyside, Middlesex, and other areas. After all had been said the CHAIRMAN said that it was evidently the unanimous feeling of the Committee that a communication should at once go out to Panel Committees urging that a stand be made on this issue.

The resolution set out at the beginning of this report was then submitted. The principal discussion took place on the proposal, should the Minister be unwilling to apply fully the Spens report to the current fee, to refer the matter back to the Spens Committee or to some other independent body. It was pointed out that there might be difficulty in reassembling the Spens Committee, and that Sir Will Spens himself was now engaged on another big task concerned with the remuneration of dentists. A motion to delete the words "or other independent body" was lost, but eventually it was agreed to put in all three alternatives—the Spens Committee itself, a representative section of it, or an agreed independent body. In this form the recommendation was unanimously adopted.

It was agreed that the recommendation be sent forthwith to the secretaries of Panel Committees, who should be requested to call meetings of insurance practitioners in their areas, also that it should be circulated as soon as possible, with an explanatory memorandum, to every insurance practitioner, and that the memorandum should make it plain that the increase to 12s. 6d.

now current had not been accepted as satisfying the demands of the profession.

The date of the Panel Conference, at which this recommendation will be the outstanding business, was fixed for Oct. 24, and it was stated that the Conference might be expected to go into a second day.

NOTE ON THE CAPITATION FEE

At no time since the inception of National Health Insurance has the capitation fee been regarded by insurance practitioners as adequate payment for the work done and the responsibility involved. In 1913 the capitation fee, including a share of the so-called "floating sixpence," was 7s. 3d. After modest increases in 1918 and 1919 it reached a level of 11s. in 1920 and 1921. In the following year it began a downward journey, reaching its lowest level in the economy years of 1931-4, at 8s. 1½d. At the outbreak of war it stood at 9s., the level determined by a Court of Inquiry the findings of which—and the evidence of the Ministry to which—caused grave dissatisfaction to insurance practitioners. In 1942 there was added an additional 9d. to cover increased practice expenses and to include an undetermined amount in respect of the inclusion of non-manual workers with incomes up to £420 per annum. In December, 1943, there was added a further 9d., "calculated with regard to the war bonus given to those in the Civil Service and others, but not strictly or rigidly calculated."

Put briefly, the 7s. 3d. of 1913 had become 9s. by 1939 and 10s. 6d. by 1946. During the years 1913-46 the average number of items of service rendered to insured persons increased threefold and the cost of living rose by 105%.

It was believed that a new phase had been reached when Mr. Ernest Brown, then Minister of Health, undertook, in response to representations by the Insurance Acts Committee, that when the war was over the whole question of the capitation fee would be investigated "from the ground up."

In May, 1944, the Ministry of Health put forward a proposal which it was stated would satisfy the promise given by Mr. Ernest Brown as well as prepare the way, in one respect, for some form of national health service. This was the proposal of the appointment of the Spens Committee to report on the appropriate range of general practitioner remuneration. As Sir John Maude stated in his letter to the Association of May 17, 1944:

It seems to the Minister that what is required is to approach the whole subject afresh and with a clear field, and in co-operation with the profession to set on foot an inquiry by a small independent committee which would arrive at useful general standards, on which future arrangements between the profession and the Minister could be confidently founded. Such a course was, you will remember, also contemplated by Mr. Ernest Brown when he gave an assurance last year that the whole question of the basic capitation fees should be re-examined "from the ground up" as soon as opportunity offered.

Sir John further stated that the results of the proposed inquiry into general practitioner remuneration "would be equally valuable and usable no matter what forms of public medical practice may continue or may come into being, under the present law or under any future legislation."

In a further letter of July 10 Sir John Maude stated that the findings of the proposed Committee would apply:

Irrespective of the institution of any National Health Service and would directly bear upon existing conditions in the present National Health Insurance scheme. The object would be, irrespective of any particular form of national service, to approach the whole subject of public remuneration of the general practitioner with an open mind and a clear field—to give effect, indeed, to the assurance given by Mr. Ernest Brown last year that the whole question of public remuneration of the general practitioner should be approached anew "from the ground up."

In the light of these promises the profession agreed to co-operate in the establishment of the Spens Committee on general practitioner remuneration. In May, 1946, the report of this Committee was issued, and without delay the profession accepted the report. The Insurance Acts Committee met the Minister of Health to ask that, in accordance with the promises given to the Committee, the report of the Spens Committee

ould be applied to "existing conditions in the present National Health Insurance scheme." In reply, the Minister stated that he could not consider the Spens Committee report in relation to the current capitation fee without first considering in relation to remuneration in the proposed new service. In effect, he was prepared to discuss current remuneration only after discussing remuneration in a service not yet established by law and not yet approved by the profession. Such a course would necessarily involve discussing future methods as well as amounts of remuneration, including the salary method.

The Insurance Acts Committee resisted the Minister's argument, maintaining that the course he proposed was neither necessary nor desirable. Insurance practitioners had received explicit Government promises that the report of the Spens Committee could be and would be applied to the National Health Insurance service, irrespective of proposals and decisions on any future service. The Insurance Acts Committee was authorized to discuss only current insurance remuneration. Questions of remuneration for the new service would be dealt with by the Negotiating Committee if and when it had been authorized by the profession. The Committee demonstrated to the Minister that the Spens Committee's conclusion that pre-war general practitioner remuneration was insufficient by an amount averaging £170 a year could, without further delay, be translated into an increase in the capitation fee. The Minister replied that, while he was willing to discuss the application of the Spens recommendations, which he accepted, both to the new health service and to the current health insurance scheme considered together, he was unwilling forthwith to apply the Spens recommendations to current insurance remuneration. Without applying the Spens recommendations the Minister proceeded to raise the capitation fee to 12s. 6d. retrospective to Jan. 1, 1946.

Bearing in mind the range and character and responsibility borne by insurance practitioners, and the economic conditions in the post-war world, the Insurance Acts Committee regards a capitation fee of 12s. 6d. as gravely inadequate. In its view the application of the findings of the Spens Committee to current remuneration would eventually mean a capitation fee which is considerably higher than 12s. 6d. It had accepted the Government's promise that, quite apart from any new service, the Spens Committee report would be applied to the current capitation fee, and it has asked repeatedly that this should be done. It was willing that the Spens Committee itself should be asked what is the appropriate interpretation of its report in relation to the current capitation fee.

All these considerations have led the Insurance Acts Committee to submit to Panel Committees the recommendation set out below, with a view to its consideration at the forthcoming Panel Conference. Panel Committees will consult individual insurance practitioners at meetings to be called for this purpose and instruct representatives to the Panel Conference. It will be observed that the resolution asks not for any specific sum but for the fulfilment of the official promises, first, that as soon as the war was over the capitation fee would be examined "from the ground up," and secondly that the Spens Committee would undertake that investigation and that its report would be applied to the current capitation fee quite independently of its application to any future service.

The recommendation which the Insurance Acts Committee has submitted for the consideration of Panel Committees and the Conference is given in the second paragraph on page 395.

ROYAL ARMY MEDICAL COLLEGE

The Royal Army Medical College is a postgraduate Service Training Institution normally confined to the teaching of officers already commissioned in the Royal Army Medical Corps and the Indian Medical Service.

Senior Officers' Course

The Senior Officers' Course, held twice yearly, is divided into three separate parts. The first part is devoted to the study of tropical medicine and entomology, military surgery, pathology, military hygiene, and psychiatry, and is spread over a period of approximately three months. Practical instruction and demonstrations are given concurrently with this part of the course. The second part includes clinical instruction in medicine and surgery at London teaching hospitals and specific fevers at the Brook Hospital, Woolwich.

This part of the course is also for a period of approximately three months. Examinations are held at the conclusion of each part of the course, and thereafter officers are selected for training in the specialist subject for which they are mostly qualified or show aptitude. The third part is up to a maximum of twelve months, and is devoted to the study of specialist subjects such as medicine, surgery, hygiene, pathology, otology, dermatology, midwifery, etc., by such officers as have qualified for further study in the preceding part of the course. The work is carried out either at the Royal Army Medical College or at a recognized teaching hospital.

Junior Officers' Course

Before the war of 1939-45, junior classes consisting of officers of the Royal Army Medical Corps and Indian Medical Service joining the Service normally began the first of February, May, September, and November, and were of approximately ten weeks' duration. This period was devoted to the study of military hygiene, pathology, tropical medicine and entomology, and military surgery. In the last week of the course examinations were arranged. These junior officers' courses are in abeyance for the time being. At the present time short intensive courses in tropical medicine, entomology and hygiene are given to officers about to go over-seas on their first appointment to Emergency Commissions in the R.A.M.C.

General

The instruction in tropical medicine includes a course of lectures and clinical demonstrations. In addition instruction in entomology is given. The Entomological Department is very well equipped with specimens and material for this purpose. Besides the teaching of tropical medicine facilities are available for carrying out research on problems of importance to Service personnel.

The principles and practice of modern military surgery are taught. Courses are held as above and deal with the surgical lessons which have been learned as a result of war experience and cover both general and regional surgery; the lectures are illustrated by visual means, pathological specimens, diagrams, slides and films, and practical demonstrations of surgical methods are arranged. The surgery of tropical diseases has its due place in the syllabus, while stress is laid on the influence of tropical diseases on the management of surgical conditions in the soldier both at home and abroad—the facilities offered by a small but very adequate Department of Anatomy, together with an excellent library of reference works and journals, are of the utmost value to these officers under instruction.

The training at the Royal Army Medical College is as varied as it is comprehensive. As regards the teaching of pathology, the syllabus of lectures for the junior and senior classes is designed to cover the subjects taught in the classes of tropical medicine, surgery, and hygiene. Specialists in pathology receive all their training, except in the performing of necropsies, at the College. The syllabus includes separate courses of lectures on bacteriology in its widest sense, serology, haematology, biochemistry, histology, and histopathology, protozoology, and helminthology. In all subjects special attention is paid to the diseases of tropical countries.

The Vaccine and Serum Departments, now separately accommodated at the Emergency Vaccine Laboratory at East Everleigh, Wiltshire, are a part of the Pathological Department of the College and are responsible for the preparation of T.A.B. and cholera vaccines for the Army and for the preparation of standard reagents for agglutination tests.

The Hygiene Department of the College, in addition to the teaching of hygiene, has facilities for the carrying out of research of importance to the Army from the hygiene point of view, and much work of this kind has been accomplished in the past, and will be a feature of the activities of the College in the future. Well-equipped laboratories of adequate capacity exist for instruction in hygiene laboratory work of all kinds. There is also a well-organized hygiene museum. Those officers taking a specialist course in hygiene are given the opportunity of taking the Diploma of Public Health and the Diploma in Tropical Medicine and Hygiene, and most of the instruction for these diplomas is given at the Royal Army Medical College.

The course in psychiatry consists of lectures partly on clinical psychiatry and psychopathology, and partly on the applications of psychological principles to morale, discipline, personnel selection, and other purely military matters. There are also demonstrations on clinical cases held at Banstead and Sutton Emergency Hospitals and demonstrations of selection tests by a Personnel Selection Officer.

The School of Radiology which exists within the College for the training of radiologists and radiographers affords ample material for teaching radiological diagnosis to officers on the course.

Courses for Other Ranks

Laboratory Assistants.—Before the war of 1939-45 a couple of eight months' training in laboratory methods—culture media, apparatus, laboratory technique, chemical analysis and hygiene—were held. The course was divided into two parts—4 months in pathology and 3 months in hygiene. Examinations were held at the end of each part.

Similar courses are at present in being at the College but in a modified form.

Correspondence

Medical Literature for Liberated Countries

SIR,—Reports and requests from U.N.R.R.A. missions in Europe make it abundantly clear that the greatest expressed need of doctors in the liberated countries is for medical literature covering the war years, so that they may bring themselves up to date with advances in unoccupied countries. From time to time appeals for medical literature for individual countries have appeared in the medical press, and the British Council, the Ministry of Information, the Royal Society of Medicine with its microfilm scheme, and other bodies have done something to cope with the problem, but as a whole the needs of Europe have hardly begun to be met. Even if U.N.R.R.A. could spend its now scanty funds on medical re-education—which it is authorized to do only in the limited sense of informing doctors how to use drugs and other medical supplies supplied by U.N.R.R.A. with which they may be unfamiliar—a special difficulty arises in the case of British medical and nursing literature on account of the paper shortage.

I am therefore appealing for complete sets of general and specialist medical and nursing journals covering approximately the war years. They should be sent to Dr. H. Hadaway, Room 1934, Health Division, U.N.R.R.A., 19, Portland Place, London, W.1 (Telephone: Langham 3090/341), and carriage will be repaid if requested. If it is felt that the sets cannot be given free of charge a price should be stated before the sets are forwarded to us, and we will try to obtain authority for their purchase. A particular request which we have so far been unable to meet is for a complete set of the *Lancet* (1939 to 1945 inclusive) for Hungary.—I am, etc.,

NEVILLE M. GOODMAN.
Director of Health,
European Regional Office, U.N.R.R.A.

London, W.1.

Sir Almroth Wright and Anti-typhoid Inoculation

SIR,—Sir Almroth Wright has just passed his eighty-fifth birthday and the *Times* has reminded us that this year is also the fiftieth anniversary of the beginning of his work on prophylactic inoculation against typhoid fever. That work was an outstanding landmark in the history of medicine not only because of its immense practical results but because it demonstrated the possibility of evaluating the changes in an inoculated person's blood which result from successful immunization. From that time immunization ceased to be a hit-and-miss procedure. Wright himself, in his first paper on the subject, was careful to point out that the idea of using prophylactic immunization against typhoid fever (and also the use of a non-living vaccine for the purpose) had come to him from Haffkine, who had applied a similar procedure in combating cholera in India. It is however beyond doubt that the whole credit for working out anti-typhoid immunization and for getting it adopted in the British Army in spite of considerable opposition from some in high places belongs to Wright.

In view of this it is surprising to read in Dr. Guthrie's recent *History of Medicine* that "During the South African War of 1899–1902 typhoid fever was a more formidable foe than the enemy and accounted for twice as many deaths as his weapons. In the Great War typhoid fever was relatively rare and even in the most unhealthy centre, that of Gallipoli, the incidence was very small, and the enormous improvement was almost entirely due to the success of anti-typhoid inoculation. This happy result may be traced to the labours of one man, Sir William Boog Leishman (1865–1926), a medical graduate of Glasgow." And in a later sentence: "Along with Sir Almroth Wright, who preceded him as Professor of Pathology in the Army Medical College at Netley and whose name is closely linked with the discovery of vaccine therapy, Leishman set himself to devise a system of inoculation against typhoid. . . ." The reference given in the above quotation is to page 1058 of Sir Harold Scott's *History of Tropical Medicine*, but it is difficult to see how the relevant sentence on that page can support Dr. Guthrie's statement. It reads as follows: "In 1897 he (Leishman) returned to England and was posted to

the Victoria Hospital, Netley, as medical officer. Netley was at that time the headquarters of the Army Medical School, later transferred to Millbank as the Royal Army Medical College. Dr. (later Sir) Almroth Wright was then Professor of Pathology and Leishman gained experience under him, and together they inaugurated inoculation against typhoid fever. He also assisted Wright in his work on anti-typhoid inoculation in the South African War and in opsonic investigations of the *Staphylococcus* and *Brucella melitensis*." On another page Sir Harold Scott refers to "Sir Almroth Wright's anti-typhoid vaccine."

It is to be noted that Wright's anti-typhoid work began in the summer of 1896 (*Lancet*, 1896, 2, 807), whereas, according to Sir Harold Scott's statement, Leishman was posted to Netley in 1897 as medical officer. It is also noteworthy that Leishman's name appears as joint author of only one of the series of five important papers on anti-typhoid inoculation published by Wright between 1897 and 1901, this one appearing in the *British Medical Journal*, 1900, 2, 122, that is, three and a half years after the beginning of the work. In order to check up my memory (not at first hand) of these events I recently wrote to one who was a pupil of Wright's at Netley and himself took part in the early work on anti-typhoid inoculation. He replied that in his view "Wright and Wright alone was the originator of anti-typhoid inoculation with killed vaccine"; and he adds that Leishman was not even on the laboratory staff at that time. "He had nothing to do with the introduction of anti-typhoid vaccine."

It would seem then that Dr. Guthrie has in some way been misinformed on this matter. I hope therefore that in honour of the greatest figure in English bacteriology this mistaken attribution of credit may be put right before it gets copied into other books.—I am, etc.,

Birmingham.

LEONARD COLEBROOK.

International Medicine

SIR,—Your article (*Supplement*, Aug. 24, p. 68) on the International Medical Conference to be held in London raises problems which I feel are of such importance to the future development of British and European medicine that I venture to make some comment on the question of international medicine. Undoubtedly German and Austrian medicine had a great influence on the practical and scientific medical outlook and progress on the Continent before Nazification brought about its decline and the war its final destruction. Great Britain should fill this gap, and it is certainly best suited to take the lead in creating something like a fellowship among the medical professions of different European nationalities.

Occasional international conferences alone, desirable as they are, will not create the bond which is necessary to achieve this aim. What is needed and what Germany and Austria used to provide is a far more personal and individual contact with the doctors and medical scientists of other countries, enabling them to receive up-to-date postgraduate training when they desired; to become conversant with the methods, progress, and problems of modern medicine, and to take home with them knowledge which will stimulate their own work and their own thoughts. The publication of abstracts of world literature is a very valuable method of making knowledge generally accessible and will be a much needed substitute for the German *Zentralblätter*, which used to be of the greatest help to anyone who was engaged in scientific work. But even this will not solve the whole problem.

It was the amount of clinical research done by workers in Germany and Austria that established the reputation of individuals and schools and induced foreign doctors to go there for instruction and work. Clinical research work in Great Britain may need some stimulus to achieve the same result. Besides this, these countries had a comprehensive scheme to attract and instruct foreign doctors, and I think some similar institution may have to be established over here. In Berlin, for instance, the following arrangements existed: (1) Regular vacation courses of five to fourteen days' duration on varying medical and surgical subjects, which were held at the Institute of Postgraduate Studies in conjunction with the big hospitals and the faculty of medicine. These courses were advertised in the foreign medical press, and foreign universities received

syllabus; the lecturers were well-known men who had the material of hospitals, sanatoria, etc., at their disposal. Several courses on different topics were held at the same time. (2) A series of individual and private courses by a number of university teachers, the list of which could be obtained abroad and which could be arranged at any time. These courses covered the whole field of medicine including practical instruction in diagnostic and therapeutic methods; each course was proposed to last for a fortnight or a month and provided first-class theoretical and practical tuition even in specialized branches of medicine. One of the attractions to the teacher is the comparatively high fee.

It would be easy to make similar arrangements in London, perhaps in connexion with the teaching hospitals, the postgraduate schools, the professional colleges, and the University. There is no place in western Europe where it could be done better. Vacation courses should be combined with visits to hospitals, social welfare institutions, research laboratories, pharmaceutical factories, etc. Some of the courses may also be arranged in French for those who do not possess sufficient knowledge of the English language. No difficulty or expense would be too great to provide Europe with an international centre of medical instruction and postgraduate teaching which is urgently needed.—I am, etc.,

London, W.1.

H. UCKO.

"The Closed Shop": a Parallel

SIR,—In the course of an admirable leader in the issue of Aug. 28 on the ethics of the "closed shop" policy the *Times* expressed the editorial view as follows: "No one can gainsay that to make a man choose between throwing up his job and joining a union is to impose a limitation on his personal freedom. To make membership of one particular union the sole passport to work in a particular industry, with incapacity to obtain employment the only alternative, is indeed a grave social decision, requiring the most powerful and cogent arguments of individual as well as social advantage before it can be justified."

Further on in the course of the leader the *Times* voiced its apprehension that the policy might spread from industry to professional occupations such as journalism: "In a wide range of professional occupations, involving the independent exercise of individual skill and judgment, the community's interest can scarcely admit the case for the closed shop. In journalism it might even invest unionists with an unwarrantable power of control over freedom of expression."

The principal objections to the "closed shop" are summarized in another passage: "The most serious objection to the closed shop, as important as the argument about personal freedom, of which it is indeed a particular facet, is the power over their members which it gives to trade unions. If in the last resort a man can leave his union with a chance of finding work, the official leaders must always have in mind the necessity to meet his needs. If he has no escape, it may well increase the temptation to undemocratic leadership, of which some already complain."

If one were to substitute "The 100% State Medical Service" or "the closed shop" and "the Minister of Health" for "the unions," could it be contended that these arguments lose any of their cogency? The position of the doctor who exercises his option to remain outside the State Medical Service seems to have received less consideration than it deserves, and there would appear to be an ominous parallelism in the "closed shop", on which our profession would do well to ponder.—I am, etc.,

Camberley.

E. S. PHIPSON.

Health Service Bill

SIR,—Reading the correspondence since the Annual Representative Meeting induces one to doubt whether the meeting was altogether a success, and whether it did in fact represent the considered opinion of the profession, especially the younger members. Many of the statements used, though greeted with loud applause, would be difficult to substantiate.

What proof is there that not every doctor will be free to enter the Service; surely the official statement during the Third Reading of the Bill was emphatic enough to confute this allegation? The remark as to the direction of doctors has

been shown to be no more than a nightmare, and to be a real improvement on the present troublesome method of getting a practice. Again, on what grounds can it be asserted that the reason for the payment of doctors by part salary is the Minister's desire to obtain more control over the profession, though he explained that to a man starting practice it might be a useful, often essential, help? We may expect an increasing number of medical men starting practice in the coming years, men who by the help of county council scholarships have been enabled to qualify, and whose parents will not be able to maintain them during their early years of making a competence. A medical man whose continued inclusion on the list is found on inquiry to be prejudicial to the Service is in no worse case than he would be under N.H.I. regulations, except in the matter of degree, though in either case his continuance in any sort of practice afterwards will be fairly unsatisfactory, his private practice only barred so far as his reputation is concerned.

If the referendum to be taken is to be the last word and the profession decides to refuse service, how are the general practitioners, especially the younger men, to subsist after the Act comes into force? Strangely, no practical discussion is recorded on this point. Incidentally, as the Minister has stated that the Service cannot be properly worked until there are many, very many, more doctors, can we bargain with him that there should be no attempt to put into practice a Service that might be discredited if not meanwhile worked satisfactorily, and (as was pointed out later by a medical man) the profession could not honestly undertake the work knowing that there would not be enough medical men to carry it out properly? There are many things in the new Service that doctors now in practice may not like, just as before 1912 they feared the Approved Societies, whose administration they now regard with satisfaction.

Than Dr. Dain no one has done more during those long years of invaluable service to the profession, so that one regrets that, on this occasion, the desire to encourage and unite the profession in a great fight persuaded him to make a fighting speech less logical than is his wont. I trust that he will not take amiss this criticism, by an old friend, of the A.R.M. just held.—I am, etc.,

Westbury, Wilts.

CHAS. E. S. FLEMING.

SIR,—I have been following with great interest the articles and letters in the *British Medical Journal* about the Health Service Bill, and now I see that it has been read a third time in the House of Commons in spite of the long and determined stand made against it by the medical profession. However, I noted that Mr. Bevan admitted that without the co-operation of the medical profession and all health workers the scheme was bound to fail.

As a lover of freedom—especially individual freedom—the freedom in which most British people ardently believe and for which they are prepared to die if need be, I have felt strongly and deeply about the struggle which the British medical profession is making against its threatened loss of freedom. At first it seemed that they had no hope against the avalanche of opposition which confronted them, just as Britain seemed lost when the Germans overran France in 1940. But then the inherent qualities which the British people possess, especially their burning love of freedom, gave them the courage, the resolution, and the stamina to withstand an almost irresistible power that threatened to overwhelm them. The brave people of the little island won eventually and saved not only their own but the freedom of the world. The medical profession of Britain, having fought for national and individual freedom during the war, now fights for the individual freedom of doctors and of patients, and for the right for each and every doctor to live and practise where he wants, to say and write what he believes to be true and best in spite of what the great and mighty may say to the contrary, and to work along lines for which he knows he has the greatest aptitude and liking and whereby he will consequently render the greatest good to the people for whom he works.

This is a great cause for which the doctors of Britain are fighting, and the medical men of the rest of the world are following the struggle very closely and with anxiety, for we all know that the main torch of individual freedom burns in

Britain. Should it be extinguished, other countries will no doubt follow Britain's example and individual freedom of action, thought, and expression in medicine will be hampered and restricted to the detriment of mankind. Knowing the sterling qualities of British doctors and their love of individual freedom, I have no doubt that the doctors of Britain will not lose in this their greatest fight of all time.—I am, etc.,

Adelaide, Cape Province, S. Africa.

F. A. LOMAX.

SIR,—I sincerely trust that the medical profession will beware of accepting such points of view as are put forward by your correspondent Dr. Peter Waddington (Aug. 31, p. 307), for he uses the very arguments which led to the Nazification of Germany—namely, that no man may think for himself but must accept whatever views are dictated by the Government of the moment. From Dr. Waddington's letter it would appear that because less than one-half of the electors in this country, voting in an election held under most abnormal conditions, returned a Labour Government to Parliament it is incumbent upon everybody, doctors or otherwise, to swallow whole anything that this Government chooses to do. It is not a question of State Medical Service versus no State Medical Service. Every political party is committed to that, and so is the B.M.A., with whom the idea really originated. Therefore we can have no quarrel with the Government for introducing the Bill. According to Dr. Waddington, however, we have no right to object to any terms which the Government may impose in the Service. We are not to take exception to the fact that the Bill entirely negatives certain basic principles which have been laid down by the profession as essential in the interests of both patient and doctor. We are not to object to placing our necks under the heel of a dictator who by the terms of the Bill takes to himself such a measure of absolute power as has never before been accorded to any Minister of the Crown. In fact we must have no voice or opinion except such as may be dictated by the powers that be. Almost every day the newspapers report strikes among various types of workers who find the terms offered to them unacceptable. Apparently doctors alone must take whatever is coming to them. The docker strikes for his democratic rights; the doctor (according to Dr. Waddington) appears to have no rights at all.—I am, etc.,

Hove.

NORMAN MAPLE.

SIR,—Dr. G. H. Urquhart's letter (Aug. 31, p. 307) is one I hope every medical man, especially the younger ones, will read. Yes, we have an opportunity which will never come again of making a firm stand against tyranny and totalitarianism, which the public and future medical men will bless us for. All through the country a fight is being put up by all classes against the threat to our rightful liberties and freedom by a power calling itself National Socialism; a power with the same name and teaching the same ideology that brought us to Germany. Surely an educated and honourable profession such as ours is not going to be caught in this trap.

The Insurance Health Act of 1912 had at least one redeeming point: it did not do away with private practice. If this Bill is accepted as it is, let there be no mistake, private practice will cease to all intents and purposes. At the will of one man or woman, whether ex-lawyer, miner, or bus-conductor, a medical man can be turned out of the Service without even right of appeal to a High Court. If this happens his position will be very serious, there will be no private practice for him to turn to and he will probably find himself conscripted into one of the fighting Services. With such a possibility threatening them may they become servile servants of the Minister and seek to curry favour in various ways, and no member of our profession should place himself in such a position. Lastly, bad as it will be for us, it will be equally bad or worse for the public, and it is for us to protect them.—I am, etc.,

Mersham.

HOWARD M. STRATFORD.

SIR,—Dr. A. H. Holmes (Aug. 24, p. 272) mentions the differing methods of remuneration—by capitation system, a salary, or payment per item of service—and by reference to the existing Midwives' Act suggests a support of the latter method from the fact that he has not heard any adverse criticism of such

legislation. I am happy to provide this for him, as such criticism embraces the necessary adjustments to existing terms of service before contentedness of working conditions is achieved.

The remuneration afforded under this Act has always been less than the minimum private fees for the varying items described therein. Of recent years an increase of remuneration has been stipulated, varying approximately from 10 to 25%, although the cost-of-living index has risen 100%. Notwithstanding, this form of administration received my sincere support, and Forms of Medical Aid received priority.

Coincident with the increase in the scale of fees I found I had to render an additional "form of account" on private note-paper, and I also found that payment rendered ceased to be itemized by the local authority. This lack of itemization rendered it impossible to check payment with accuracy, although it became apparent over a period of time that a steady deduction from the accounts rendered had taken place. Insistence on itemization of accounts paid then revealed the fact that these deductions had occurred without notification and solely according to how the local authority had accepted or interpreted the Act. A typical instance of such deduction is the rendering of an account for an obstructed labour for which summons was issued and which was treated with priority, and the payment for treatment of a post-partum haemorrhage and ruptured perineum which was effected, the original emergency for which summons was issued having passed before arrival at the case. There is a 50% difference between the remuneration of the differing items.

The Minister concerned is not able to offer direction to the local authority regarding amendments in their methods of business administration, and he rules that a practitioner is not paid for the emergency for which he is summoned but for the emergency or otherwise which he finds on arrival at the case.

Surely no one but an overt masochist would work under such terms and conditions, considering that private fees are already reduced in order to assist the functioning of the Act. There furthermore cannot be any logic in such ruling when, as in the case of a dependant of a member of H.M. Forces, the private fee is refunded.—I am, etc.,

Tipton.

L. H. EUNSON.

SIR,—The point that refusal to join the new Service would not be flouting the law has been made on several occasions, but I do not consider that sufficient consideration has been given to this fact in relation to the proposed plebiscite on: Should negotiations on regulations be made? A "Yes" to this question may be given by doctors who subsequently will not join the Service because the negotiations may not meet with their approval. A "No" may come from doctors who will subsequently join the Service because there may be negotiations which will meet with their approval. The "Yes" or "No" is a personal decision taking many external factors and a prophecy of the future into consideration, and the percentages of "Yes" and "No" are a potent factor controlling the future if they mean anything. But would they mean anything real? The percentages expressed by the simple issue of the plebiscite may be changed on the day of reckoning, and therefore, though the answer is an attempt to control the future, it is known that the answer may be a totally unreliable control of the future. Surely a paradox?

For the plebiscite to be of any real value as a mandate for the Council it is necessary that further questions be asked, and one at least of these further questions must be entirely different for those who answer "Yes" and those who answer "No" to the simple question. To the "Noes": "If negotiations do take place do you intend to join a Service the form of which has been agreed between the Minister and the profession by consultation mainly in accordance with the expressed principles of the profession?" To the "Ayes": "If negotiations do not take place do you intend to join a Service the form of which has been decided mainly by the Minister in accordance with the control conferred on him by the Bill?" I consider these questions to be essential for clarification of the wishes of the medical profession, but further questions would be useful—e.g., "If you are in a 25% minority will you co-operate with the majority?" "Do you consider that the interests of doctor and community could be better served by a national organization than they are now?"

The above part of my letter should be read in conjunction with the excellent letters by Dr. E. W. Broster (Aug. 10, p. 206), Dr. Ayton-Ormston and Dr. Brown (Aug. 24, p. 273).

I am entirely in agreement with the spirit of the Bill and with the spirit of the principles of the profession, but I disagree with much of the letter of the Bill and with little of the letter of the principles of the profession. Dr. Collier (Aug. 31, p. 308) has drawn attention to the soundness of Principle 2, but I would like to show my dislike for the wording of Principle 5—"Every registered medical practitioner should be entitled as a right to participate in the public service"—why "right"? If doctors demand rights then the public and the Minister will demand their rights. Only the community has rights, and these exist only when individuals submerge their rights and do what is right for the community. The spirit of Principle 5 is that doctors should be free to join or leave the Service according to the current interests of the community, but the wording demands participation (perhaps of the salary without any work) anywhere at any time, even contrary to the interests of the public and the Minister. Surely the wording and the spirit could be better expressed than at present?—I am, etc.,

Birkenhead.

ALEX. M. FRASER.

SIR,—The Minister of Health stated in the House of Commons that "in a recent plebiscite there were a majority of doctors in favour of the abolition of the sale and purchase of practices" (*Hansard*, July 26, col. 473). This may be untrue, but no denial was made in the House, and I have seen nothing from the Public Relations Officer of the B.M.A. in the Press. On the other hand the Chairman of Council, Dr. Guy Dain, stated that the voting of the Annual Representative Meeting on this issue was 12 in favour and 229 against. This is the Principle 1 referred to, and the matter should be made clear at once.

It is difficult to believe that doctors will part with the goodwill of their practices to the State for paper money the value of which now stands at only one-third of its purchasing power in 1911 and must depreciate further with a profligate Government. Whether they are foolish enough to do so or not, the difference in the statement of the Minister and that of the Chairman of Council should be made clear, so that even a Member of Parliament may know the facts, and the dictator refuted.—I am, etc.,

Beckenham.

A. E. BLACKBURN.

Principle 2 and the Health Service

SIR,—Dr. Howard E. Collier (Aug. 31, p. 308) writes: "In my opinion Principle 2 is the only solid ground on which opposition to the new Service can be rightly undertaken, and that only after the Act has been given a trial." This means presumably that we should agree to eat, sleep, and work in handcuffs in order to find out how we like it. If we find such control irksome we must then get the handcuffs removed. But will this be possible once Mr. Aneurin Bevan has snapped them on and removed the key? Even a tame rabbit would hesitate to be so foolish.—I am, etc.,

Bournemouth.

MARGARET VIVIAN.

Health Service Bill and the Public

SIR,—In the impending struggle over the National Health Service Bill it is vitally important that we as a profession should carry public opinion with us. Unfortunately two things are rather painfully obvious. First, that while most people think highly of their own doctor they have nothing like as good an opinion of doctors in the mass. Secondly, that we have not on the whole had a good press, while many of the things said against us in the press are based on misunderstandings of our ideals and motives. If we could transform this situation we could transform our whole outlook.

The silly part of it all is that we could have an excellent press if we went the right way about it. I have discussed this matter with a number of journalists—and journalists as a whole are men who know just how many beans make five—and they are unanimous in asserting that we doctors not only hide our

light under a bushel but go to a lot of trouble to blow the thing right out.

Day-to-day medical life in practice and in hospital is crammed full of what Fleet Street calls human stories—stories which if published would raise the public estimation of our profession right up to the skies and get us anything we care to ask. As random examples, there are hospitals which get 80% of five-year cures of cancer. There are hospitals and clinics which take rheumatic workers who would otherwise be crippled and restore them to their jobs; there are doctors and hospitals researching into analgesia in childbirth; there are doctors in colliery districts who risk their lives after explosions going to attend accidents; and many, many other things which could and should be told.

Medicine is no longer a "mystery." It is part of the life of every citizen, and he wants to know about it. But what happens? First, such stories are carefully concealed. If they are told in the medical press they are disguised in scientific language, embellished with statistical tables, and made incomprehensible to the man in the Fleet Street office who is diligently yawning his way through the current medical periodicals in search of a story. Secondly, if he is a really bright boy and glimpses a story, woe betide him. He approaches the hospital or the doctor concerned and has the temerity to ask for an interview. Horror! We do not talk to the lay press. We slam the door in the nasty man's face, repress a shudder, and hope to heaven no one saw him about the place. And then we wonder why doctors don't get a good press!

We act like this for two reasons. First, we have been trained scientifically to loathe premature publication and to avoid any imaginative embellishment on the cold hard facts. Secondly, we are terrified of being accused of advertising and finding ourselves in Hallam Street. As long as we continue to run away from these two bogies we shall have a bad press, and public opinion will not be behind us as it should. If we want to win our fight we must alter all this, and we must do it now.

First, it must be realized that the general public are not very willing to read unembellished cold fact. They like jam on their bun, and the journalist's job is to provide the jam. It is no use being squeamish about this. If the story of what doctors do for the people of this country is to get across at all it will only get across with the jam on it. Secondly, this bogey about advertising. It is a hoodoo. Any doctor who really wants to advertise himself can and does get away with it. There is the tactful gossip paragraph, there is the righteous disclaimer. It can be done, but so few think it worth while that it is ridiculous to make every doctor afraid on that account of seeing his name appear in the press. If the G.M.C. wishes to further the interests of the profession as a whole it can here and now declare that it doesn't give a damn if every doctor in England has his name in the papers. It will need a great effort by the G.M.C., but it is an effort they should make.

Then, Sir, if you and the editors of other medical papers could give a half-column a week to the sort of stories the lay press is avid for in language the lay press can understand I vow it will not be many weeks before the man in the street will be saying: "These doctors are damn good fellows. Let's see they don't get a dirty deal. They know their own job superlatively well. Let them run it."—I am, etc.,

Ashted.

W. EDWARDS.

* * Part of the trouble is that the journalist's jam is taken by him and by the lay public as the bun.—ED., *B.M.J.*

Medicine and Economics

SIR,—Our noble profession seems to be in a rather ignoble condition at present. The portals of entry to the profession are choked with applicants while at the same time hundreds of energetic young doctors are unemployed. On the other hand the established general practitioner knows only too well that constant overwork is the only way to maintain an income sufficient for his modest needs. Thus we have the position that whereas there are too few doctors for the work awaiting them there are far too many doctors for the money available to pay them. It is of course the low rate of insurance capitation which is cramping general practice. A considerable increase (I do not mean two shillings) would secure employment for all these young doctors. General practitioners are

longing for assistants, whom they cannot afford to pay at present. We are in the midst of circumstances where the onlooker possibly sees most of the game. I take off my hat to our philanthropic colleagues who represent us on divisional, branch, and central committees, whose breakfast tables are snowed under by reports of Hansard, headquarters' circulars, and all the rest of it. Yet I fear they cannot see the wood for trees.

Success in general practice does not necessarily endow a man with the qualities required to tackle an experienced politician such as a Cabinet Minister. Sending a deputation from the Insurance Acts Committee to interview a Minister of Health is like sending lambs to the slaughter. The I.A.C. should take expert advice from an economist. He would give them the rights of it inside a day or two. The plan of action should then be entrusted to a skilled agitator for its execution. This advice will come hard to the I.A.C. Twenty years of practice, issuing dogmatic instructions to patients who do not know enough to criticize or assess the information given, does not imbue a doctor with humility. Most of us consider ourselves qualified to express an opinion on anything from motor-cars to Mozart. This form of conceit has cost us dearly in the past, and I say again that we should pay for expert advice.

In asking for a substantial increase in capitation our agitator will have the solidity of all panel doctors behind him. If we fail to secure a concession from the Minister on this point how are we to secure alterations or modifications in the Health Bill when 60% of doctors think one way and 40% the opposite? I consider that the present dispute on the capitation fee is a show-down. If the Minister does not concede the modest 15s. in the face of the findings of the Spens Committee and the unity of panel practitioners he will never concede anything in the future, and we shall know our power to be nil.—I am, etc.,

Preston.

ROBERT SLATER.

Disabled Persons Act, 1944

SIR,—While welcoming the further publicity given to the Disabled Persons Act by your article (Aug. 24, p. 268), I would like to comment on some continued misconceptions. This is important since the successful launching of the Act largely depends on all doctors concerned being first well informed and later co-operating. As in other forms of enlightenment, the medical journals have a primary function. It is therefore with some anxiety and regret that I note your mixed blessing on this scheme to guarantee employment for the disabled person.

The Act itself has really evolved as a compulsory application of the King's Roll, whose success was limited to ex-Servicemen of the first world war and to good employers who felt a moral obligation in employing handicapped soldiers. Other employers shirked their responsibility to the community by skimming the cream off the labour market and leaving the handicapped workers as "unemployables" and a permanent drain on the nation. They might have found some justification for this skimming process during periods of high unemployment. However, in wartime and its continued emergency of export drive, and, we hope, in the future cornucopia of promised full employment, these "unemployables" become at least of economic value, apart from a national responsibility. Thus the labour which the bad employer complains of having "dumped" on him and thus "interfering with his selection of workers" is merely his quota of obligations to the community. During wartime, remember similar complaints against fire-watching and Home Guard—and the same attempt at shirking? The good employer, i.e., the most efficient, has used good personnel management in placing the man in the job which suited him.

Regarding the managerial encouragement of eligible workers to register, your article has got the wrong end of the stick. In this factory the handicapped worker is advised by the industrial medical officer (who is also a member of the local disablement committee) to become registered. The shop stewards, who have trade union representatives on the same local committee, support the medical advice. The personnel manager further encourages the worker by presenting his registration as an assurance that in time of redundancy the enrolled worker will be more likely to retain his job, all other factors being equal. The scheme here is working to the satisfaction of the worker,

the employer, and the local doctors. Many consultants in hospitals are already advising enrolment as part of treatment in necessary cases.

It may be of interest that in this factory the largest diagnostic group on this modern "King's Roll" is peptic ulcer at 28%; second is cardiovascular at 18%; and then arm or leg injury or disease at 10% each. This dominance of peptic ulcers supports the first article in your *Journal* of the same date by Gainsborough and Slater, in which they state "more attention should be paid to the use of resettlement facilities under the Disabled Persons Act . . ." in preventing the expected relapse of peptic ulcers. These percentages, and those given by Sir Reginald Watson Jones, also show that the hard core of those who cannot compete with the able-bodied in open competition is probably under 5%. Thus the development of the special corporations for sheltered industry is not, as you state, "the real solution to the real problem," as the percentage is so small. This sheltered industry is only for the dregs at the bottom of the barrel.

There is however some reasonable criticism that can be offered. The first group of Disablement Rehabilitation Officers tends to be staid, middle-aged officials from the Ministry of Labour. Probably there is no other immediate source of recruits for the novel role of D.R.O. This first group appears keen and enthusiastic in reducing the birth pains of the new Act, but I feel that there should be some test of human aptitude for this new job, followed by training for at least two years. If possible the future D.R.O. seems to require a social conscience, a nursing or hospital background, and an inside knowledge of industry from apprenticeship. Thus instead of a mixed welcome for this new form of King's Roll we might more profitably conserve our emotion for sympathy, education, and encouragement for the present D.R.O., whose position is so vital a link in this scheme to guarantee suitable employment and placing for all disabled persons.—I am, etc.,

Little Lever, near Bolton.

Tobacco and Ulcer Dyspepsia

SIR,—The statistical article on "Tobacco and Ulcer Dyspepsia" by Mr. R. A. Jamieson, Prof. C. F. W. Illingworth, and Dr. L. D. W. Scott (Aug. 31, p. 287), prompts me to make a few observations which I hope are not irrelevant. The writers of the article do not appear to have taken into consideration the fact that cigarette-smoking is the mark of the lean, tense, anxious; hyperchlorhydric individual who is liable to develop and suffer from a peptic ulcer; the heavier his cigarette consumption the more can this constitution be undermined and the greater the proneness to ulcer dyspepsia. The pipe smoker on the other hand is usually an older man who has reverted to the infantile suckling instinct. He is placid, comfortable, and probably hypochlorhydric. Considering he swallows his nicotine in mouthfuls it is surprising more damage is not done. Of course he does not inhale as does the cigarette smoker. The young man begins smoking a pipe as part of a character act. It may become a habit later and it is often an aid to thought. He has not the same constitutional flaws as the cigarette smoker and is usually thoughtful and tolerant. What of the cigarette smokers who have not and never will have dyspepsia? These people usually smoke for social reasons, especially in company, with drinks and after dinner. They are of the herd. Witness the groping for cigarettes and the flaring of lights all over a cinema when an actor lights a cigarette. The uninterested non-smoker (not the rigid obsessional individual who turns his back on earthly pleasures), too, is usually a placid easygoing fellow with no psychosomatic ailments.

Thus to my mind the smoking of cigarettes is a symptom and the nicotine-stained hands a sign of the ulcer diathesis, and the relationship between smoking and ulcer dyspepsia only apparent. It would be interesting to know how far the greatly increased smoking by women has affected the male/female ulcer ratio. It is well to remember that the last inch of the cigarette contains four or five times as much nicotine as the first inch—its own content plus the nicotine condensed from the other two burnt inches. The man with the nicotine-stained hands who tenaciously smokes his cigarette to the very end is the

ompromising nicotine addict and takes it in big doses. The
ly nervous smoker should be encouraged to find other out-
for his emotional tension. Chewing gum would be a better
native "tic."

In conclusion I have wondered that ulcer cases will readily
up beer but obstinately refuse to give up cigarettes.
ough both tend to produce hyperchlorhydria yet the
ner's ability to sedate as well as release emotional tension
interacts the harm it might do as a gastric irritant and
nulant.—I am, etc.,

Yale Naval Hospital, Yarmouth.

ANTHONY C. HAMER.

Treatment of Lupus Vulgaris by Calciferol

SIR,—As reviewer of the *B.M.J.* for the *British Journal of
Dermatology and Syphilis* I feel it my duty to point out an
error in your issue of Aug. 31, (p. 300). Writing on *The 1945
Year Book of Dermatology and Syphilology* your reviewer
states: "Perhaps, however, 1945 will stand out in the history
of dermatology as the year in which the treatment of lupus
vulgaris by calciferol was first instituted, and that method,
initially tried by Dowling at St. Thomas's, London, appears to
have been published too late for mention in the year book
before us." This treatment for lupus vulgaris was first used
in France by Charpy in 1941, though Dowling, who indepen-
dently began this method in 1943, was, owing to the war,
initially unaware of Charpy's work and has made generous
acknowledgment in his papers of the Frenchman's priority.—
I am, etc.,

Jimburah

G. A. GRANT PETERKIN.

Reiter's Disease

SIR,—Drs. R. N. Herson and Frank Marsh both remark
(Aug. 24, p. 275) that the trend of symptoms, polyarthritis,
conjunctivitis, and conjunctivitis noted in my article (Aug. 10, p. 197)
being characteristic of Reiter's disease may also be associated
with bacillary dysentery. Of this I was aware. The suggestion
that the identity of Reiter's disease with dysenteric complications
has previously been made by Dr. P. Manson-Bahr, *Bull. War
ed.*, 1944, 4, 653. That this may in fact be true I do not deny
because of such a possibility I called my article "The syndrome
known as Reiter's disease", but it seems to me very unlikely
cause (1) in only a few cases of Reiter's disease does diarrhoea
occur; (2) in no case in the very considerable literature on this
syndrome in Germany and America has the dysenteric bacillus
been identified (for full list of references see *Archives Inter-
ed.*, 1946, 77, 295); and (3) bacillary dysentery was unknown
in the Bahamas—neither had the three patients whose stories
accounted any history of a diarrhoeic attack of dysenteric type.
Naturally because a similar syndrome may occur as a
dysenteric sequela it does not follow that such a syndrome
always possesses such an aetiology. The characteristic signs
may in fact be part of a gonococcal infection, and it is in the
distinction from this that the importance of the recognition of
the Reiter's disease syndrome exists.—I am, etc.,

Penlow Camp.

Fl.-Lieut., R.A.F.V.R.

Penicillin and Nasal Sinus Infections

SIR,—In the literature on penicillin therapy there is some-
what half-hearted commendation on its value in the treatment
of nasal sinus infections. The references are largely to its local
application in various ways including replacement therapy, and
have not seen references to its systemic administration. My
experience with penicillin in the treatment of chronic sinus
infections leads me to conclude that in the treatment of this
condition penicillin represents a very notable advance.

I have had a chronic sinus infection since 1915. This was
operated upon in 1922, but with only partial success, and I
have had the usual symptoms of a chronic infected antral sinus
with nasal discharge of muco-pus and general vasomotor hyper-
sensitivity. Treatment with sulphonamides brought about a
considerable degree of symptomatic relief, but I became sensi-
tized to the sulphonamide group. Discharge from the nose was
examined by a well-known bacteriologist, and it was reported
to contain a penicillin-sensitive strain of *Staphylococcus aureus*.

In communication with Glaxo Laboratories earlier this year,
it was pointed out to me that penicillin could be supplied to a
degree of purity such that very large single doses up to 500,000
units could be given intramuscularly. I was supplied with some
of this material, and four intramuscular injections of 500,000
units were given at 24-hour intervals. Each injection was given
in 3 ml. of sterile water, and there was practically no discomfort
from the injections. The relief from the nasal symptoms was
remarkably rapid. The discharge of muco-pus diminished
markedly within four days, and the symptoms of hyper-
sensitivity also cleared up. Ten days after the treatment a
bacteriological examination was again made, and the *Staph.
aureus* was reported as absent. Whether or not this result will
be permanent remains to be seen, but if reinfection did occur
at a later date then I would unhesitatingly repeat the same
treatment.

I have heard of several other cases which have received
benefit in acute and chronic sinus infections from a few massive
injections of penicillin. My experience from this treatment
makes me urge a further trial. Chronic sinus infection is a
common and distressing complaint, and treatment has never
been wholly satisfactory. The substantial improvement that
may be obtained from a few injections of penicillin would I
think place sinus infections as one of the more important
indications for penicillin therapy.—I am, etc.,

Bournemouth.

J. ROSS MACMAHON.

"Cord Round the Neck"

SIR,—The question as to possible strangling by the cord of
the baby as it is born must I think be answered in the positive.
I and a district nurse delivered a child two days ago whose
cord was tightly wrapped three times round the neck; the cord
was thick and healthy, but luckily forty inches long (measured).
The nurse was quick to put on two pairs of forceps and help
me to divide the second loop of the cord after I had slipped
down the first loop. The reason why I consider death of the
foetus possible if no help had been at hand is that when the
next expulsion pain came on the cord became so tightly con-
stricted round the neck that division was absolutely necessary
owing to the force of the contraction, and unless the placenta
had separated very quickly choking was bound to occur. This
delivery was preceded by apparently inexplicable delay in the
rupture of membranes during strong pains, and doubtless the
reason for this was the artificial shortening of even this long
cord by means of the previous winding round and round the
foetus.

As a matter of medical jurisprudence here we have yet
another reason for considering concealment of pregnancy a
serious crime: not to obtain help at the time of birth may
be serious to the life of the infant.—I am, etc.,

Coldingham.

F. O. TAYLOR.

The Apparently Acute Abdomen in Pulmonary Tuberculosis

SIR,—Twice in the last three months I have been called to
see patients who have been known to have pulmonary tubercu-
losis and who have complained of abdominal pain of sudden
onset and great severity. On examination they both had board-
like rigidity of the abdomen with diffuse agonizing pain, and
obviously thought their last hour had come. In one case the
duty medical officer happened to be of surgical bent and had
already called in an anaesthetist to ascertain the patient's fitness
for operation, having made a diagnosis of perforated tubercu-
lous ulcer of the bowel. Now in both cases some common
features presented themselves. It had been a hot day. Both
patients were drenched in sweat as they both had advanced
phthisis with high fever, and there is little doubt in my mind
that their pain was of a similar aetiology to miners' cramp. I
have seen similar abdominal pain in the sweating stage follow-
ing a malarial rigor, and before I became familiar with the
condition these cases caused me a good deal of worry.

The treatment is table salt given in orangeade, about 2 dr.
to a pint (8 g. to 568 ml.)

I should like to thank Dr. G. E. Beaumont for his helpful
criticism and advice.—I am, etc.,

Chelms.

F. E. DE W. CAYLEY.

Obituary

H. L. H. SCHÜTZE, M.D.

The death is announced from Switzerland on Aug. 9 of HARRIE LESLIE HUGO SCHÜTZE, assistant bacteriologist to the Lister Institute of Preventive Medicine. Schütze, who was the son of John and Caroline Schütze, was born in Melbourne, Australia, in 1882 and was educated at Brackley, Cumlodon, and at Melbourne University, where he obtained the degrees of M.B., B.S. He was assistant bacteriologist to Melbourne University in 1905 and later completed his medical education in Germany, where he obtained the M.D. degree of Würzburg in 1907. He was assistant at the Institute of Hygiene there up to 1912, when he obtained a Beit Fellowship and took up research work at the Lister Institute, London. He joined the staff of the Institute as assistant bacteriologist in 1913.

Schütze's scientific work was chiefly devoted to the serological analysis of bacteria in relation to taxonomy. His paper which appeared in the *Lancet* in 1920 on the typing of what was afterwards known as the *Salmonella* group was of fundamental importance, and the types that he then described were used later by Bruce White and others as the primary basis of their studies. He was chairman of the *Salmonella* Sub-committee of the Nomenclature Committee of the International Association of Microbiologists from its inception. In 1928 he unravelled the complicated antigenic structure of the flagellated *Pasteurella*, *Pasteurella pseudotuberculosis* (*Bact. pseudotuberculosis rodentium*) and showed that the flagellar H antigen, which is formed only in cultures grown at 6°C. or lower, is common to all strains within the species, but that the somatic antigens are more complex and may be used as taxonomic criteria. He also carried out important studies on other members of the *Pasteurella* group. In the case of *P. pestis*, for example, he demonstrated that there are only two antigens—one corresponding to the envelope and the other to the somatic substance. He contributed noteworthy articles on *Pasteurella séptica* and on *Pasteurella pseudotuberculosis* to the Medical Research Council's *System of Bacteriology* and collaborated with the late Sir John Ledingham in the paper on the production of active immunity to bacterial and virus infections of man and animals which appeared in the same publication. For a number of years Schütze was in charge of the Vaccine Department of the Lister Institute, both at Chelsea and later at Elstree, where he worked during the second World War. After the war he returned to Chelsea and devoted his whole time to research.

He had a many-sided character and, apart from science, was deeply interested in literature, music, and the drama. He was an accomplished linguist and greatly loved to wander about Europe on vacation with his devoted wife, helping her to collect material for her numerous and successful novels. He made many friends in the varied aspects of life that he touched and his untimely death will leave a very definite gap in their affections. He married in 1913 Gladys Henrieta ("Henrietta Leslie"), the only child of Arthur and Mary Raphael. There were no children of this happy marriage, which was terminated by the death of Mrs. Schütze, also in Switzerland, only a few weeks ago.

R. ST. J. B.

A friend writes: Your epitome of OTTO MAY's career (Aug. 31, p. 314) was marvellously accurate and true, and must have awakened a chord of affection among his many friends. These loved him for what he was. With perhaps pardonable intrusion may one of those not-so-"brilliant young men" who came down from Cambridge in the early years of this century join in the chorus of gratitude and tribute to his memory. Especially would he recall those happy carefree days when F. J. Cleminson and Otto May did so much for those of us who through lack of aptitude or application found the toils of anatomy and physiology so difficult to combat. This illustrious pair by their wisdom, ability, and human understanding brought many of us safely over the ordeal of the 2nd M.B.—an achievement for which we are for ever grateful. Those early associations in Cambridge were the beginning of closer ties of friendship in London and will always be reckoned as the happiest and most valued part of our student days.

Universities and Colleges

UNIVERSITY OF LONDON

THE LONDON HOSPITAL

It was announced on Sept. 4 at the quarterly Court of the Governors of London Hospital that Miss Dorothy Russell, M.D., Sc.D., had been appointed to succeed Prof. Hubert Turnbull, who retires as Director of the Bernhard Baron Institute of Pathology at the end of this month after 40 years' service with the hospital. Dr. Russell has also been appointed Professor of Morbid Anatomy by London University at the London Hospital.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following candidates have been approved at the examination indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN PUBLIC HEALTH.—*S. G. Abelson, O. Adeniyi-Jones, *A. Anderson, A. E. Brown, J. M. Brown, E. J. Bury, *A. L. Cochrane, W. C. Cockburn, E. R. Dansie, R. D. Dewar, W. Y. Fettes, C. W. Gordon, C. G. Hunter, M. T. I. Jones, Sung-Jui Liao, M. J. Lowther, J. P. P. Mackey, A. H. M. Richards, E. M. Rowland, Alice C. N. Swanson, G. H. Taylor, J. Watkins-Pitchford.

* With distinction.

UNIVERSITY OF GLASGOW

David Fyfe Anderson, M.D., F.R.F.P.S., F.R.C.O.G., has been appointed to the Muirhead Chair of Obstetrics and Gynaecology in the University.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Faculty, with Dr. Geoffrey B. Fleming, Visitor, in the chair, A. Allison, M.B., Ch.B., C. D. Anderson, M.B., B.Chir., J. D. O. Kerr, M.B., Ch.B., and R. A. Shanks, M.B., Ch.B., were admitted Fellows *qua* physician, and E. A. Chisholm, M.B., Ch.B., J. Hutchinson, M.B., Ch.B., A. McDougall, M.B., Ch.B., J. M. McInroy, M.B., Ch.B., W. Magauran, M.B., Ch.B., F.R.C.S.Ed., and J. C. Walker, M.B., Ch.B., were admitted as Fellows *qua* surgeon.

Medical News

From Nov. 1, 1946, Dr. N. Hamilton Fairley, C.B.E., F.R.S., who takes up his appointment as Wellcome Professor of Tropical Medicine in the University of London, will cease to be Director of the Wellcome Laboratories of Tropical Medicine, but will become consultant in tropical medicine to the Wellcome Foundation. Brig. John S. K. Boyd, O.B.E., at present Director of Pathology, War Office, will become Director of the Wellcome Laboratories of Tropical Medicine.

A meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Friday, Sept. 20, at 3.15 p.m., when Dr. Honor Smith will read a paper on "Some Clinical and Pathological Aspects of Tuberculosis of the C.N.S." At 5 p.m., papers will be read by Dr. G. B. Dowling on "Treatment of Lupus Vulgaris" and by Dr. D. E. Macrae on "Use of Calciferol in Tuberculous Conditions."

The Paddington Division of the B.M.A. is arranging a special meeting in Room 140 at the County Hall, Westminster Bridge, S.E., on Tuesday, Sept. 24, at 3 p.m., when papers will be read on the causes and prevention of prematurity by Dr. R. Lovell, Prof. F. J. Browne, and Prof. L. S. Bemrose, followed by a discussion. In view of the importance of the subject it is hoped that non-members as well as members from other Divisions will be present.

A course of lectures in skin diseases will be held at the London School of Dermatology, St. John's Hospital for Diseases of the Skin, 5, Lisle Street, Leicester Square, W.C., on Tuesdays and Thursdays, at 5 p.m., from Oct. 1 to Dec. 12.

The ninth annual Louis Gross Memorial Lecture will be delivered under the auspices of the Montreal Clinical Society at the Jewish General Hospital, Montreal, on Wednesday, Oct. 16, at 8.30 p.m., by Dr. Roy R. Grinker, director of the Institute for Psychosomatic and Psychiatric Research and Training of the Michael Reese Hospital, Chicago. His subject is "Psychiatric Objectives of our Time."

The prize-giving ceremony at the London (Royal Free Hospital) School of Medicine for Women will be held in the Great Hall of B.M.A. House, Tavistock Square, on Tuesday, Oct. 1, at 3 o'clock. Prof. Winifred Cullis will deliver the inaugural address for the session 1946-7.

the following have been added to the list of persons entitled to type "K" coupon-equivalent certificates for the provision of active clothing: A person authorized by the Ministry of Health, Clerk to the Council of the Chartered Society of Physiotherapy, Registrar of the Board of Registration of Medical Auxiliaries, Secretary of the B.M.A., and the Hon. Secretary of the N. and District Dental War Committee.

Cardinal Griffin, Archbishop of Westminster, at the opening of London centre of the Catholic Marriage Advisory Council on 1. 3, said that at this centre, and at others to be established, Catholic husbands and wives could obtain advice and guidance in their marital difficulties. It would also try to keep the need for successful marriages and parenthood in the minds of all concerned by every available method of publicity.

Medical men from Norway, Brazil, and Chile have arrived in London to study subjects in which they are specialists, and programmes have been arranged for them by the British Council. Dr. K. Thomassen, a Norwegian physician who has specialized in tuberculosis, is spending September here. Dr. Odair Pacheco Rosa, of the University of Sao Paulo Medical School, arrived from Sao Paulo on Aug. 30 for a two-month visit to study hospital planning and administration. Prof. Alexandre Lipschutz, who is here to work in the field of cancer and to lecture on his own experimental work on tumours, is a director of the centre for experimental medicine in the National Health Service of Chile.

Vienna, with a population of 1,500,000, is one of the few towns in Europe to-day with a surplus of doctors. It is estimated that there are as many as 3,000—of whom approximately half have private clinics and the other half function in various hospitals. Of 1,500 hospital doctors, probably only two-thirds will remain in Vienna to settle down. There are about 1,500 doctors, however, who are still prisoners of war, hoping to return soon, and of these at least a third will stay in Vienna, which will bring the number up to 3,000 again. The same number of doctors have left the country for political reasons. Medical students in Vienna number as many as 3,800.

Dr. F. T. H. Wood, O.B.E., Medical Officer of Health, Bootle, Merseyside, has been elected chairman of the Council of the Royal Sanitary Institute, to take office on Oct. 1.

Mr. W. Rowley Bristow, F.R.C.S., has been awarded the Rank of Chevalier in the Légion d'Honneur and a "Citation à l'Ordre de la Santé."

EPIDEMIOLOGICAL NOTES

Discussion of Table

England and Wales 285 notifications of diphtheria were recorded during the week—an increase of 34 on the preceding week, which was chiefly due to increases of 12 in Liverpool B. and of 8 in Berkshire. Measles, whooping-cough, and scarlet fever declined with decreases of 572, 39, and 25 respectively. Decreases were also observed in the notifications of dysentery and typhoid—18 and 17 respectively.

Notwithstanding the fall in the total whooping-cough notifications there was considerable variation throughout the country; the most marked differences were increases of 38 in Warwickshire, 24 in Essex, and 18 each in Staffordshire and Durham.

An increase in the notification of measles was observed in Berkshire and was due mainly to 21 cases being reported from Islampstead R.D. compared with 5 in the previous week. Similarly in Hertfordshire and Durham fairly large increases were recorded—36 and 34 respectively. In the former county Albans M.B. was responsible for an increase of 7 and Watford R.D. for 15 cases. In Durham increases of 11, 11, and 21 were reported from South Shields C.B., Billingham D., and Hartlepool M.B. respectively.

In Scotland a rise of 9 was reported in the notification of scarlet fever. Forty-five cases of erysipelas were notified—an increase of 18 and the highest notification for twelve weeks. The majority of cases were reported from Lanarkshire and Inverclyde.

No fresh cases of typhoid were reported. There were 13 new cases of dysentery.

In Eire there were 20 fewer cases of diarrhoea and enteritis, largely due to the decline in Dublin C.B., from which 19 cases are reported as compared with 37 in the preceding week.

Week Ending August 31

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 744, whooping-cough 976, diphtheria 262, measles 1,565, acute pneumonia 279, cerebrospinal fever 41, dysentery 74, acute poliomyelitis 21, paratyphoid 44, typhoid 27.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 24.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

ANY QUESTIONS?

Unsuccessful Vaccination

Q.—A child aged three months was unsuccessfully vaccinated against smallpox thrice at intervals of about two weeks. The lymph was fresh and obtained from reliable sources. Does this mean that the child possesses permanent immunity against smallpox? Or is this immunity only of a temporary nature derived from the mother? If so, does the child require re-vaccination?

A.—An unsuccessful vaccination is not proof of insusceptibility to smallpox. A case has been reported recently of a soldier who had been vaccinated no fewer than ten times, always unsuccessfully, during the twelve months before he died of haemorrhagic smallpox.

True inherited absolute immunity against smallpox, which is but temporary, occurs only among infants born of variolous mothers or of women who have themselves lately undergone successful vaccination. It is not uncommon for primary vaccination to fail to take in a susceptible infant. If a successful result has not been obtained after three attempts at intervals of ten to fourteen days, and if the degree of risk of exposure to smallpox infection warrants some delay, further series of attempts should be made at about three-monthly intervals. In the event of prolonged apparent insusceptibility to vaccinia a change of technique, the use of multiple insertions, and the choice of a different site for the inoculations should be considered; but the operator should not be satisfied until success has crowned his efforts. It goes without saying that the quality of the lymph should be above suspicion.

Purpura in the Elderly

Q.—For some time I have had erratic subcutaneous haemorrhages on the back of my hands, varying in size from a florin to a crown. There is no pain and they usually disappear within a week, leaving a brown stain. Though I am an old man my health is good. Can you explain these happenings?

A.—The description of these lesions corresponds exactly to what is called "senile purpura"—if the questioner will forgive this term. It is a well-recognized condition and was first described by Thomas Bateman in his *Practical Synopsis of Cutaneous Disease* (London, 1818). The histology was studied by Unna (*Arch. Dermatol. Syph.*, 1895, 33, 200), who found that the haemorrhages occurred either by rhexis or diapedesis into the degenerate senile skin from the smaller and often sclerotic vessels. Senile purpura is benign, associated with no other haemorrhagic phenomena, and carries no sinister implication. It commonly occurs on the back of the hands and forearms where the skin in the elderly is often atrophic and lax. There is no satisfactory treatment, and it must be regarded as one of the tiresome but harmless accompaniments of increasing years.

Castor Oil for Summer Diarrhoea

Q.—Is the practice of swallowing a dose of castor oil for the treatment of any and every form of summer diarrhoea justified by present-day knowledge of the physiological and pathological flora of the alimentary tract?

A.—The present-day knowledge of the aetiology of summer diarrhoea is not sufficiently complete to make any very didactic

statements, but the routine use of castor oil in every case in infancy does not appear to be justified. It was based on the assumption that (a) there was an irritant in the gut which should be expelled, (b) the subsequent action of castor oil was a constipating one. When parenteral infection is the primary cause of summer diarrhoea castor oil is useless, and when an enteric infection is present (e.g., Sonne dysentery) there are more specific means of treatment available. The use of castor oil might well be reserved for older infants and children who are known to have eaten a specific gastro-intestinal irritant.

Sore Tongue in Pernicious Anaemia

Q.—What is the treatment of a persistently severe sore tongue in a case of pernicious anaemia? The patient has had adequate treatment with liver parenterally, and large doses of all the vitamins.

A.—It is most unusual for soreness of the tongue to persist in adequately treated pernicious anaemia. Minot and Murphy in their original paper found that this symptom disappeared early and that its recurrence almost always indicated inadequate treatment. The same observation was made by Oatway and Middleton (*Arch. intern. Med.*, 1932, 49, 860) who stressed the importance of this sign as showing inadequate dosage or advancing neurological disease. It would therefore be worth while doubling the dose of liver extract and perhaps changing to one of the cruder products unless the patient is already receiving such a preparation.

The other possibility is that the glossitis is unrelated to the anaemia in this case. Sore tongue has been relieved both by nicotinic acid 150 mg. daily, and riboflavin 10 mg. daily; but this patient has apparently had all the vitamins. Leukoplakia in an early stage is another possibility.

Finally, cases of glossitis do occur which cannot be explained and which do not respond to treatment. The pain can be relieved by mouth washes of 1% pantocaine before meals.

Trilene Administration

Q.—In the *Journal* of July 6 a method of using trilene with Hewitt's modification of Claver's inhaler is described. As I cannot obtain this can you recommend any other simple apparatus?

A.—Trilene and air can be used either for self-administered analgesia or for light anaesthesia. Freedman's inhaler is a simple and efficient method of providing analgesia by the patient's inspirations being drawn over the surface of the liquid. The inhaler was designed for midwifery but can be used for almost any purpose except dentistry, where the mouth must be free. For these cases Hill's nasal inhaler is useful. The patient blows air from a rubber hand-bulb through the trilene bottle to a nose-piece.

If anaesthesia is necessary Marrett's vaporizer can be employed. This is a "draw-over" apparatus with an adjustment for varying the concentration of trilene vapour. If a gas and oxygen apparatus is available trilene can be placed in the chloroform bottle and added in minimal amounts to the mixed gases. Care must be taken not to give an overdose or tachypnoea will ensue.

The Colour-blind Driver

Q.—If one discovers red-green colour blindness in an otherwise healthy person should one certify that he is unfit to drive a public service vehicle? Is there any statement on this subject in the *Road Traffic Act*?

A.—Colour blindness is not specifically mentioned in the questionnaire which the doctor is required to answer, but among other things he has to declare generally whether he considers the candidate's vision a likely source of danger. In answering this question he would undertake serious responsibility if he made no mention of the colour blindness, but he is presumably entitled, having mentioned it, to say that he does not consider it a source of danger—though the question appears to involve important non-medical factors. Such cases are in practice very rare. The licensing authority would probably give the candidate a special test. The matter is not dealt with in the Act, which merely empowers the Minister to make appropriate regulations. These are published in S.R.O., 1934, No. 1321.

Painless Labour

*Have any of the leading obstetricians personally confirmed Dr. Granly Dick Read's methods of ensuring painless childbirth in normal labours as described in his book *Childbirth*?*

Most obstetricians agree with the principles underlying Dr. Read's methods and believe that the management of labour as he suggests is conducive to easier and more painless labour. However, there are few if any who would go as far as to agree that the application of such methods, except in the very occasional susceptible patient, results in the labour being entirely painless.

Gouty Deposits

A female patient aged 69 suffers from attacks of gout affecting the great toe and thumb. This is a clinical diagnosis confirmed biochemically. From time to time small, hard, white nodules appear on the palmar surfaces of the fingers. These nodules soften and when incised yield a substance the colour and consistency of "off-white" paint, which contains polyphosphate cells but no organisms. What is this condition?

The description suggests that the fluid contains sodium urate crystals, and if these are found the diagnosis of gout is confirmed. In long-standing cases of gout the sodium urate is deposited in the cartilages of the joints, along the tendons, and in the subcutaneous tissues. In the latter situation deposits are liable to cause local inflammation, which may ulcerate through the skin and discharge the "white matter". A skiagraph of the hand would also settle the diagnosis.

Sterilization with Penicillin

Would one or two penicillin lozenges dissolved in a pint of milk help towards its sterilization? Or would the acidity or alkalinity of the milk render it inert?

Unless the milk were already almost unfit for consumption its reaction would not be a serious obstacle. There are others of more importance. The lesser of these is the dependence of the bactericidal action of penicillin on temperature: the lower this is the less would the effect be. The greater difficulty is the varied flora with which the penicillin would have to contend. We know of no information about the susceptibility to penicillin of the various bacteria concerned in souring of milk, but it is very likely that some of them would be much more resistant than pathogenic Gram-positive bacteria. If coliform bacilli were present, as they commonly are in unsatisfactory milk, they would not only grow in spite of the presence of penicillin but would destroy it. Penicillin is only in certain circumstances sterilize milk: it could only reduce numbers of bacteria or prevent their further growth. In certain circumstances it surely remains a duty only to use penicillin for the treatment of disease, and in cases where there is no reasonable expectation of benefit. To degrade such a substance by trying to make it compensate for unhygienic methods of producing milk would be a waste of the worst kind.

Congenital Pyloric Stenosis

Please enlighten me on the aetiology (particularly the predisposing factors) of congenital pyloric stenosis.

Congenital pyloric stenosis is undoubtedly inherited, but uncertain whether the disorder is recessive or dominant. Cases of large numbers indicate a higher degree of cousin marriages among the parents than would be expected on a random sample of the population, which favours a recessive inheritance. On the other hand recorded instances of a child and parent both having the disorder are not uncommon, and there have been published which give the appearance of dominant inheritance. The condition has been found at birth and in a foetus, so that the cause must be prenatal and not due to feeding or any postnatal factor. Some disorder of the autonomic system is usually postulated, but it is also said that a so-called hypertrophied muscle is abnormally packed with collagen, as is found in Von Gierke's disease.

INCOME TAX

Car Transaction

D. N. bought car A while acting as an assistant and in receipt of an (untaxed) car allowance. On being called up to the R.A.M.C. he sold the car, and in November, 1945, bought car B. He resumed the assistantship in January, 1946, and became a partner in the practice in April, 1946.

* No deduction can be claimed for the purchase of the car at a time when he was not professionally engaged. In the circumstances D. N. will have to confine his claim to the depreciation allowance for 1946-47.

Income Arising in a Dominion

"ANTIPODEAN" states: "I am at present living and earning income in this country but my domicile is in New Zealand." He has investments in a Dominion on which he pays income tax there; so far no remittances have been made to the United Kingdom. What is his position as regards British income tax?

* In the case of any person who satisfies the Commissioners of Inland Revenue (as presumably "Antipodean" can do if required) that he is not domiciled in the United Kingdom, tax is payable not, as in other cases, on the amount arising abroad, but on the sums which have been or will be received in the United Kingdom. In the circumstances "Antipodean" need not include the income in his British income tax return unless and until some amount is received in this country. As the law now stands he will then be liable to British tax, less the appropriate Dominion income tax relief, and the amount of the remittance in so far as it is covered by income arising abroad while he is in the United Kingdom.

LETTERS, NOTES, ETC.

Mites in Sputum

Dr. REGINALD FISHER (King's Langley) writes: Perhaps it may be of interest to record that in 1913 I found mites in the sputum of a case of lung abscess following empyema in a man who had never been out of England. In one specimen I found the detached leg of a mite, in another a complete insect somewhat resembling a cheese mite. Up to now I have thought of these as contaminants.

Medical Service in Australia

Dr. IAN GILLILAND (Hessle) writes: Sir Ernest Graham-Little builds up a strong case in his letter (Aug. 24, p. 272) on information which he received from a colleague in Canberra. This states "that an Act embodying the socialist aspirations for a State Medical Service was passed some years ago by the Socialist Government" of Australia. This statement came as a considerable surprise to many. Sharing this surprise, the editor of the *Medical World* wrote to the High Commissioner of the Commonwealth of Australia and received the following information: "I have to advise you that no Bill to establish a State Medical Service has been introduced into the Commonwealth Parliament of Australia." In view of this contradiction and of the importance attached to the whole episode by Sir Ernest Graham-Little, I feel that a further explanation is called for.

Children in Nurseries

"E. D. F." writes: With reference to Mrs. G. M. Woolf's letter (Aug. 31, p. 318), fifteen years ago I worked in a voluntary day-nursery. There it was customary to use small squares of old linen for nasal hygiene, burning the soiled ones immediately. Recently on return to nursery work I was again confronted with the never-ending problem of nasal catarrh. By regular morning cleaning of each child's nostrils, and by the use of hard-baked rusks, there was great improvement. Possibly the exercising of the nasal and oral passages kept the "huns on the run."

The Late Dr. E. H. van Someren

An obituary notice and appreciation of Dr. E. H. van Someren, who died at Syracuse, appeared in the *Journal* of March 15, 1943. Distress has been caused to his family by the wholly erroneous statement in a recent book of memoirs that Dr. van Someren suffered from melancholia and committed suicide.

Correction

Mr. HARRY FREEMAN writes: My letter in the *B.M.J.*, 1945, 2, 510, states that "the oesophagus is deficient behind in the upper 1½ in., there being a dehiscence of the inner longitudinal fibres." This should read the "outer longitudinal fibres," and Dr. C. Allan Birch very kindly drew my attention to this clerical error on my part.

H.M. Forces Appointments

ARMY

Col. R. R. G. Atkins, O.B.E., M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brig.
Lieut.-Col. H. T. Findlay, from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. J. C. Denvir has retired on retired pay and has been granted the honorary rank of Col.

Lieut.-Col. G. G. Drummond, having attained the age of retirement, is retained on the Active List supernumerary.

Majors (War Subs. Lieut.-Cols.) S. W. K. Arundell and A. N. T. Meneces, C.B.E., D.S.O., to be Lieut.-Cols.

Short Service Commissions.—War Subs. Major G. G. Smith has retired and has been granted the honorary rank of Lieut.-Col. Capt. S. P. Bellmaine has retired and has been granted the honorary rank of Major.

War Subs. Major W. Thomson has retired and has been granted the honorary rank of Major. (Substituted for the notification in a *Supplement* to the *London Gazette* dated June 25).

Capt. T. G. A. L. Warrington has been appointed to a permanent commission.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Subs. Major W. C. Barber, T.D., to be Major.

Lieut. A. D. M. Greenfield, supernumerary for service with University of London Senior Training Corps (Med. Unit) has resigned his commission.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Lieut.-Col. J. P. Fehily has relinquished his commission and has been granted the honorary rank of Col.

War Subs. Capt. P. Esmonde and B. G. Hill have relinquished their commissions and have been granted the honorary rank of Major.

The notification regarding Lieut. D. L. Cran in a *Supplement* to the *London Gazette* dated June 28, has been cancelled.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Miss) I. W. Simpson has relinquished her commission on account of disability and has been granted the honorary rank of Capt.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

E. J. Radley-Smith to be Squad.-Ldr. (Emergency).

Fl.-Lieut. (Temp. Squad.-Ldr.) J. H. McElney has resigned his commission retaining the rank of Squad.-Ldr.

Fl.-Lieut. K. P. G. Mears has resigned his commission retaining the rank of Squad.-Ldr.

To be Fl.-Lieuts. (Emergency): P. Dawson-Edwards, W. T. W. Paxton, and R. M. MacKenzie.

To be Flying Officers (Emergency): D. N. Baron, B. Dover, Clark, G. Clayton, E. J. L. Davies, J. H. Edworthy, A. S. Hughes, J. G. Jackson, M. C. Joseph, A. C. Parry, M.C.; E. R. Smith, T. Taylor, R. R. Trussell, and T. R. E. Pilkington.

The notification regarding D. C. Bodenham in a *Supplement* to the *London Gazette* dated July 9, has been cancelled.

INDIAN MEDICAL DEPARTMENT

Capt. A. R. Bell, A. R. D'Abreu, W. A. Browne, E. R. Hill, A. C. S. Mann, and P. W. Emmett to be Majors.

Lieuts. P. W. Emmett, P. F. Fanaken, G. S. Rozario, A. St. C. Bartley, A. N. De Monte, M.B.E., M.C., C. H. W. Windsor, M.B.E., R. T. M. Hayter, M.B.E., J. C. Mendis, M. J. Godfrey, M. J. Nicholas, and H. G. M. Campbell to be Capt. S.

First Class Assistant Surgeons J. R. Cartner, W. E. Rodgers, W. J. Rowe, J. S. E. Barnard, C. A. Martin, A. E. A. Phaire, C. F. Vieyra, R. O. A. Smith, B. St. C. F. Lynsdale, A. L. G. Allen, A. A. Feegrade, and S. A. De Souza to be Lieuts.

Dr. George F. Lull, former Deputy Surgeon-General of the United States Army, on April 1 of this year succeeded Dr. Olin West as General Secretary and Manager of the American Medical Association. Dr. West became General Secretary of the A.M.A. on the retirement of Dr. George H. Simmons in 1924. He had been previously an executive officer of the Tennessee State Board of Health and Director for the Rockefeller Sanitary Commission and International Health Board in Tennessee.

Association Notices

Middlemore Prize

The Middlemore Prize consists of a cheque for £50 and illuminated certificate, and was founded in 1880 by the Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize the year 1947 to the author of the best essay on: "Aetiology and Treatment of Chronic Iridocyclitis." Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London W.C.1, on or before Dec. 31, 1946. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1947.

Meetings of Branches and Divisions

EASTBOURNE DIVISION

At a recent meeting concern was expressed by various members about the general and local shortage of midwives.

A resolution, "That in the opinion of this Division in view of the grave shortage of midwives the period of their training should be reduced to six months," was carried unanimously.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m., Dr. McK X-ray Treatment in Diseases of the Skin.

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Th Edinburgh Royal Infirmary, Thurs., 4.30 p.m., Dr. H. L. W Care of the Small Premature Infant.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—8 p.m., Dr. W. O. G. Taylor, Aetiology and Treatment of Paralytic Squint.

LIVERPOOL HEART HOSPITAL.—Mon., 3.30 p.m., Dr. Harris, Blood Pressure; 4.30 p.m., Dr. Doyle, Congenital Heart Disease. Tues., 3.30 p.m., Dr. Hibbert, Fundus Appearances in Se and use of the Ophthalmoscope; 4.30 p.m., Prof. R. A. M Modes of Action of Vitamins. Wed., 3.30 p.m., Dr. I (i) Cardiac Arrhythmias; 4.30 p.m., Dr. Datnow, (i) Constitutional Complications of Pregnancy. Thurs., 3.30 p.m. and 4.30 Dr. Harris, Ward Round. Fri., 3.30 p.m., Dr. Doyle, Col Thrombosis; 4.30 p.m., Dr. Arundel, Tonsil Affections in Relation to Rheumatic and Cardiac Conditions.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the advertiser, and should reach the Advertisement Manager not later than first post on the morning.

BIRTHS

CHILD.—On September 5, 1946, at the Radcliffe Infirmary, Oxford, to (née Bond), wife of Dr. J. P. Child, a son—David Laurie.

FRANKLIN.—On September 1, 1946, at Edgware, to Margaret (née N) wife of Dr. C. B. Franklin, a son.

JOHNSON.—On August 30, 1946, at University College Hospital, to Gwen (née Galpin), wife of Dr. S. J. Johnson, a son.

MACGARRY.—On August 26, 1946, at Isall Nursing Home, Llandudno, to (née Hiltermann), wife of Dr. P. V. MacGarry, Ipoh, Malayan Union, a daughter—Gelda Margaret.

MACGREGOR.—On September 5, 1946, at Kilmarnock Burgh Maternity to Rosa F. MacGregor, M.B., Ch.B. (née McLaren), wife of Dr. I MacGregor, a daughter—Gelda Margaret.

McGUFFIE.—On September 5, 1946, at Westbay Nursing Home, Dur Gwendoline Mary (née Sturrock, M.B., Ch.B.), wife of S. M. N M.B., Ch.B., a son.

PICKARD.—On August 31, 1946, to Daphne, wife of H. M. Pickard, Endsleigh Court, W.C.1, a daughter.

ROGERSON.—On August 30, 1946, at Bark Hill House, Whitechurch, Sh to Drs. Gerard and Evelyn Rogerson, a daughter.

THE.—On August 25, 1946, at Nuffield House, Guy's Hospital, to wife of Dr. I. T. Thé, a son—Robert.

WYANT.—On July 27, 1946, at Leicester, to Anne (née Dunnett) and Colonel G. M. Wyant, R.A.M.C., a son.

MARRIAGES

DILLON-BAILEY-THOMSON.—On July 25, 1946, in Nottingham, John Dillon, M.B., B.Ch., to Joyce Doreen Bailey-Thomson, M.B., Ch.B.

DEATHS

MITCHELL.—On August 26, 1946, at Rothay Garth, Ambleside, West Thomas Houghton Mitchell, M.D., in his 84th year.

LONDON SATURDAY SEPTEMBER 21 1946

THE INCIDENCE, INCUBATION PERIOD, AND SYMPTOMATOLOGY OF HOMOLOGOUS SERUM JAUNDICE*

BY

NANCY SPURLING

JOHN SHONE

JANET VAUGHAN

Jaundice has been recognized with increasing frequency as a sequela of transfusion with whole blood, plasma, or serum (Memorandum, Ministry of Health, 1943; *B.M.J.*, leading article, 1944, 1945). It is generally agreed that such jaundice is indistinguishable from, and of the same aetiology as, the jaundice following the use of convalescent serum, vaccines containing human serum, and syringes contaminated with human blood (Memorandum, Ministry of Health, 1945). This jaundice is commonly called homologous serum jaundice.

Since certain of the cases reported after transfusion have proved fatal it appeared important to determine, if possible, the incidence of this complication, since it might well be that the risk of hepatic necrosis was greater than the risk incurred by withholding transfusion. Records of blood products issued from the N.W. London area since 1940 being available, a follow-up of patients who had received transfusions in this area was therefore instituted in 1944 with a view to determining the incidence of homologous serum jaundice following transfusion, its incubation period, and the symptomatology.

Method of Investigation

Follow-up

In connexion with an earlier investigation, blood, serum, or plasma issued from the depot carried a label. The hospital receiving and using the bottle was asked to fill in answers to certain questions on the label before returning it to the depot. The returned labels were filed ready for reference. The greater part of the information so collected was not relevant to the present inquiry, but the batch number of the material used was entered on the label before issue, and subsequently the name of the hospital and patient, so affording means of following up all those transfused.

In view of the latent period that may occur before the development of jaundice no personal follow-up of a patient was attempted until five months after the date of the transfusion. The hospital was then visited and the patient was interrogated if still in hospital. If discharged, his address was obtained and he was sent a follow-up letter (Appendix I) asking, among other things, whether he had had an attack of jaundice. If an affirmative answer was received the patient was visited and a more elaborate form (Appendix II) was filled in. In two cases, when the patient lived at a great distance, the general practitioner was asked to complete this form. For obvious reasons it was impossible to include cases of sub-clinical jaundice in a follow-up of the character described. The notes of all patients who died between forty days and seven months of transfusion were checked to determine if death was due to hepatic necrosis, and to ascertain that no attack of jaundice had occurred in the intervening period. At the time the investigation was started the possible significance of a syringe in the transmission of an icterogenic agent was not appreciated, and no note was made as to whether casualties had, for instance, received penicillin (Darmady and Hardwick, 1945) or penicillin (Turner, 1946). The data were not available

to allow a follow-up of the donors of batches which proved to be icterogenic, in order to determine if they had recently had jaundice.

Products Transfused

In the first instance, patients who had received serum and plasma were followed up. In many cases such patients had received blood in addition. The serum and plasma came from 400 different pools, varying in size from 30 to 200 litres. Subsequently a series of patients who had received only blood was studied. It is unfortunate that all patients cannot be placed in clear-cut groups as having received only one product, but the majority of serum and plasma transfusions were given to air-raid casualties treated under emergency conditions. Such transfusions were an essential life-saving procedure, and were not given as part of a planned experiment.

Geographical Distribution of Patients

An attempt was made to follow up all patients known to have been transfused with serum or plasma in 78 hospitals in the N.W. London area between 1940 and July, 1945. Patients receiving only blood in 1944 and the first half of 1945 were traced from 23 hospitals. A few earlier patients were included in this group.

Control Series

Simultaneously with the follow-up of patients receiving whole blood a survey of a control group was made to assess the incidence of jaundice in the non-transfused hospital patient. This group was composed of patients in the same hospital at the same time as the patients given blood. For every transfused patient a control was selected of the same age group, sex, and, if possible, in the same ward, but regardless of diagnosis. The age groups taken were 0-19 years, 20-39 years, 40-59 years, and 60 years and over. No control cases were followed up until five months after discharge from hospital. They were then either visited or written to, asking them to complete a questionnaire not unlike that sent to patients who had received transfusions.

Character of Patients

The majority of patients given serum or plasma were civilian air-raid casualties; this accounts for the large proportion of deaths within two months. Death in many cases occurred within a few hours, or at most days, of receiving a transfusion. Most of the patients given whole blood were maternity and gynaecological cases; a large group of patients with haematemesis, and other miscellaneous medical and surgical cases, were, however, included.

Results of Follow-up of Patients Given Serum and/or Plasma

In this group a total of 2,040 patients were followed up. Since jaundice occurred after both serum and plasma no distinction is made between the two in tabulating the results, nor is any distinction made between patients who also received blood and those who did not. It may be stated, however, that a more detailed analysis of the figures showed that jaundice occurred with any combination. The numbers involved were

* A report to the Medical Research Council from the North-West London Blood Supply Depot.

too small to allow conclusions to be drawn as to whether any combination was more likely than another to cause jaundice. The results are shown in Table I. Of the 2,040 patients 9%

TABLE I.—Particulars of Patients given Serum and/or Plasma

Total no. of patients followed up	2,040
No. of patients not traced	186
Proportion not traced	9%
No. of patients traced	1,854
No. of patients who died within five months of transfusion	800
Proportion of traced patients who died within five months of transfusion	43%
No. of surviving patients upon whom the incidence of jaundice is based	1,054 (100%)
No. of patients with no history of jaundice within five months of transfusion	963 (91.4%)
No. of patients who developed jaundice within five months of transfusion	77 (7.3%)
No. of patients who developed jaundice, but doubtful if due to transfusion	14 (1.3%)
(See Appendix III)	

could not be traced. A much larger proportion—43% of those traced—had died before it could be determined whether or not they would develop jaundice after their transfusion. The time at which death occurred after transfusion in the 800 patients who died before the five-months period was complete is shown in Table II. The observed incidence of post-transfusion jaun-

TABLE II.—Analysis of Time of Deaths

Time	Deaths
Under 2 months after transfusion	769 (96.2%)
2-3	16 (2.0%)
3-4	5 (0.6%)
4-5	10 (1.2%)
	800 (100%)

dice following serum and plasma has therefore to be based upon approximately half those originally exposed to risk. The great majority of deaths—769—however, took place shortly after transfusion, and there is no reason to suppose that the inevitable absence of evidence relating to them would affect the relative incidence, or that if they had lived they would have been either more or less likely to develop jaundice than the survivors. Of the surviving 1,054 patients 91.4% gave no history of jaundice within 5 months; 77 (7.3%) gave a history suggestive of homologous serum jaundice; and 14 (1.3%) developed jaundice which could be attributed to other causes, such as malignant disease or exposure to a case of infective hepatitis (see Appendix III).

The 31 patients who died between two and five months after transfusion had time in which to develop jaundice, but were not exposed for the full five months. If, however, these 31 patients be debited with a full exposure, the observed incidence of 7.3% would only be reduced to 7.1%, so that they can but little difference to the upshot.

Untraced cases raise the more difficult point whether a patient is more or less likely to have had jaundice. For example, it might be more difficult to trace a patient who had died, and such a patient might have died of jaundice. With these provisos the figures show an incidence rate of jaundice of 7.3% within five months of transfusion with serum and/or plasma.

Certain pools of both serum and plasma were found to be more icterogenic than others, although in no case was it possible to trace every bottle of one particular pool. For example, of 29 traced patients transfused from one pool of serum (LS6), 9 (31%) gave no history of jaundice, 9 (31%) subsequently developed jaundice within five months of transfusion, and 1 (3.4%) had a doubtful attack. The remaining 10 patients died within five months of transfusion. In all, 38 bottles were involved, 13 (30%) being given to patients who did not develop jaundice, 11 (28%) to the patients who did, and 1 (2%) to the patient who had the doubtful attack. The remaining 13 bottles were given to the patients who died. In contrast, only 1 or 2% of the patients transfused from other pools subsequently developed jaundice. To some slight extent, but not entirely, this may be attributed to the fact that as soon as the risk of jaundice was appreciated, when two or more patients were found to have developed jaundice following transfusion

from any one pool, the remaining bottles were withdrawn from circulation, thus curtailing the further risk of jaundice.

Character of Jaundice

Of the 77 cases of jaundice investigated, only one was serious, the patient being in a comatose condition for several days. No deaths occurred among the proved cases of post-transfusion jaundice, and two occurred in the doubtful group, one of these being a patient with carcinoma of the bronchus and the second an old man of 86, said to have died of senile decay, with jaundice and bronchitis as secondary causes. The ages of the 77 patients developing jaundice varied from 4 to 80 years, 30 patients being males and 47 females. The incubation period varied from 45 to 150 days, the majority of cases occurring 60 to 90 days after transfusion (see Graph).

The incubation period in homologous serum jaundice

Symptoms

The incidence of symptoms other than jaundice in 77 cases of jaundice is shown in Table III.

TABLE III.—Incidence of Symptoms

Vomiting	41	Urticaria	5
Depression	20	Joint pains	19
Skin rashes	16		

Seventeen patients complained only of slight nausea or lassitude accompanied by pale stools, dark urine, and a yellow tinge of skin and sclerotics.

Results of Follow-up of Patients Given Whole Blood

In this group 1,284 patients were followed up. They received between them 3,468 bottles of blood. The results are shown in Tables IV and V. The number of patients surviving upon

TABLE IV.—Particulars of Patients given Whole Blood

Total no. of patients followed up	1,284
(No. of bottles, 3,468)	
No. of patients not traced	170
(No. of bottles, 404)	
Proportion not traced	13%
No. of patients traced	1,114
(No. of bottles, 3,064)	
No. of patients who died within five months of transfusion	223
(No. of bottles, 786)	
Proportion of traced patients who died within five months of transfusion	20%
No. of surviving patients upon whom the incidence of jaundice is based	891 (100%)
(No. of bottles, 2,278)

(No. of bottles, 30)	
(See Appendix IV)	

whom the incidence rate is based was 891, receiving between them 2,278 bottles of blood. No patient receiving whole blood developed frank homologous serum jaundice. Notes on 6 doubtful cases are shown in Appendix IV.

TABLE V.—Analysis of Time of Death

Time	Deaths
Under 2 months after transfusion (No. of bottles, 679)	192 (85%)
2-3 months after transfusion (No. of bottles, 36)	13 (5.8%)
3-4 months after transfusion (No. of bottles, 54)	13 (5.8%)
4-5 months after transfusion (No. of bottles, 17)	5 (2.2%)
Total	223 (100%)

Among patients receiving blood a larger proportion have been untraceable than among the patients receiving serum and/or plasma. The death rate in this group, however, is lower, and the observed incidence of post-transfusion jaundice is therefore based upon a larger proportion of patients exposed to risk than in the previous group.

Controls

In this group no case of jaundice within five months of discharge from hospital was noted, although two patients developed jaundice ten months and five and a half months respectively after discharge. Neither of these could give any history of contact with a case of jaundice. Both complained of vomiting, depression, and dark urine accompanied by icterus; and in each case the attack was mild. Results are shown in Table VI. Although the death rate in this group

TABLE VI.—Particulars of Control Patients

No. of surviving patients upon whom the incidence of jaundice is based	811 (100%)
No. of patients with no history of jaundice within five months of discharge from hospital	809 (99.6%)
No. of patients who developed jaundice within five months	Nil
No. of patients who developed jaundice six months or more after discharge	2 (0.4%)

is low, the evidence on which the figures are based is poor owing to the high lapse rate—i.e., persons who could not be traced.

Discussion

The results recorded above show an incidence rate of 7.3% of cases developing jaundice after transfusion with serum and/or plasma. No proved case of jaundice following transfusion with whole blood was found. The number of patients given whole blood was smaller than that given serum, but the figures suggest that the risk of homologous serum jaundice is less with whole blood than with pooled serum and/or plasma.

Though no comparable series has been reported, the present findings are in accord with those of other workers, who have almost all been concerned to describe actual cases which developed jaundice after transfusion rather than to assess the incidence of this complication. Jaundice following whole blood appears to be less frequent than jaundice following pooled serum and/or plasma.

Beeson (1943) reported four cases in which jaundice resulted from small transfusions of whole blood within four months, and three cases after the use of plasma. Steiner (1944) records three cases following whole blood alone and two following plasma also. Rappaport (1945), in a series of 33 cases of jaundice after transfusion, mentions two who were given blood only. Loutit and Maunsell (1945) found no case of frank homologous serum jaundice in a follow-up of a selected series of 213 blood transfusions. They record two doubtful cases only. Apart from the cases mentioned above, many which followed the use of pooled serum and/or plasma, either for transfusion or other purposes, have been reviewed at intervals (Memorandum, Ministry of Health, 1943; Bradley *et al.*, 1944; *B.M.J.*, leading article, 1944; *B.M.J.*, leading article, 1945).

The evidence available therefore supports the conclusion to be drawn from the present observations—namely, that jaundice occurs more commonly after serum and/or plasma than after blood. It is obvious, however, that it is easier to

incriminate a batch of serum or plasma as the cause than it is to incriminate a bottle of blood, since multiple cases may occur after the use of a batch of the former material, while in the case of blood it is extremely rare for one donor to give blood to more than one recipient within an appreciable time. Unless a single donor's blood results in jaundice of the recipient on repeated occasions it is unsafe to assume that the blood is icterogenic.

It appears probable, on the other hand, that the difference in incidence is not due to any inherent differences between blood and serum or plasma, but rather to the fact that serum and plasma are prepared from big pools and therefore many more patients are likely to receive the icterogenic agent from one donor than when all the affected material is given to one patient, as in the case of a blood transfusion.

Loutit and Maunsell (1945) have shown that no case of homologous serum jaundice was detected when 99 individual sera were each injected into an average of six normal recipients. Transmission experiments have shown, however, that a single serum may be an effective transmitter of jaundice (MacCallum and Bauer, 1944; Neeffe *et al.*, 1944; Paul *et al.*, 1945).

The findings of the present inquiry, therefore, emphasize the recommendation of Loutit and Maunsell (1945) that sera for prophylactic use should preferably be individual sera, and that for transfusion purposes pools should be as small as possible. The present observations also stress the importance of labelling with the batch number all material issued, of keeping accurate records of its destination and use, and of creating some machinery for notifying to the regional transfusion officer cases of jaundice following transfusion, so that if necessary the suspected serum or plasma may be withdrawn from circulation. Since certain batches are known to have infected 57% of the cases exposed (Bradley *et al.*, 1944), withdrawal of an infected batch at an early stage should do much to reduce the incidence of jaundice. At present this somewhat cumbersome procedure appears essential, since icterogenic batches cannot be detected by any laboratory or animal test.

The incubation period accorded with that previously noted, varying from 45 to 150 days, the majority of cases occurring between 60 and 90 days after transfusion—so demonstrating yet again the remarkable difference between the incubation period of infective hepatitis and homologous serum jaundice.

The character of the jaundice in the 77 cases here recorded has already been discussed in detail. It was, with one exception, mild. This is in accord with the majority of other observers (Bradley *et al.*, 1944; *B.M.J.*, leading article, 1944; Loutit and Maunsell, 1945), but it must not be forgotten that a definite mortality after both transfusion jaundice and "syringe jaundice" has been noted (Droller, 1945). Few, if any, of the cases were bad enough to go to hospital or to be attended closely by their own doctor; the account of their symptoms is therefore neither detailed nor extremely reliable. It does not differ in any striking way from that described by previous observers (Steiner, 1944; Rappaport, 1945).

Summary

The results are given of a follow-up of 2,040 patients transfused with pooled serum and/or plasma, of 1,234 patients transfused with whole blood only, and of 1,234 control patients, not transfused, who were in hospital at the same time as those receiving whole blood.

The incidence of jaundice in the patients receiving pooled plasma or serum was 7.3%. No patient receiving whole blood developed frank homologous serum jaundice. There was no case of jaundice among the controls within five months of transfusion.

The character of the jaundice was with one exception mild. The symptomatology and incubation period noted were in accord with previous accounts.

It is suggested that to minimize the risk of homologous serum jaundice after transfusion the following procedure should be adopted: (i) human serum for prophylactic purposes should not be pooled; (ii) for transfusion purposes only small pools should be used; (iii) all blood products issued should carry an identification number; (iv) records should be kept of the number of any bottle given to a particular patient; (v) machinery should be maintained and strengthened for the notification to the regional transfusion officer of jaundice following transfusion, thus enabling icterogenic material to be withdrawn from circulation.

*We understand that only small pools are now used by the Ministry of Health for the preparation of blood products.

POST-OPERATIVE ACTIVITY AND RESUMPTION OF NORMAL MOVEMENT

THEIR INFLUENCE ON EMBOLISM AND THROMBOSIS

BY

GIBBON FITZGIBBON, M.D., F.R.C.P.I., F.R.C.O.G.

In recent medical literature there is a definite tendency to advocate an increase in activity after operations, especially laparotomies, as a prophylactic against complications such as embolus. Various systems of exercises to be carried out daily are suggested; most of them need the personal supervision of the nursing staff and include massage, being thus inevitably restricted in application and time-wasting for the attendants.

When I started obstetrics in the Rotunda Hospital in 1902 I very soon recognized that many of the women cared for in the extern maternity department were up and about their rooms from the second day, and puerperal complications were probably less frequent in that department than in the intern. Jellitt (1912) in his first Rotunda Hospital report (1910-11) says: "All patients who have had a normal confinement without perineal laceration and suture may be allowed and encouraged to sit up in bed after the first twelve hours. Further, they may get out of bed to pass water if they wish to do so. After 48 hours they must get out of bed to pass water at least twice in 24 hours, unless their general health contraindicates their doing so. . . . After 72 hours they may take a few steps . . . or sit for a few minutes . . . the time they remain up being gradually increased each time they leave bed." In his second report he says, "I have made no change in this plan, and I have found it most satisfactory. I cannot find the smallest evidence that it has been anything but beneficial to the patients."

In my first report (1919-20) I stated (FitzGibbon, 1921): "All cases showing a rise of temperature are got to sit up in bed frequently during the day, to go on to their hands and knees to micturate, or even to get out of bed for this and for defaecation. I think this method of promoting uterine drainage is of the greatest importance, and far more to be depended upon than the mere elevation of the top of the bed." I repeat this in my second report (FitzGibbon, 1922), adding, "although all cases are encouraged to do this from the first day of the puerperium"; and in my third report (FitzGibbon, 1923a) I say, "Sitting up does not mean Fowler's position, which I think is very little use for uterine drainage. The position should be complete sitting, with the body a little forward of the vertical; it should never be maintained for long or after the patient feels . . . tired. She should then lie down and rest completely. Ten or fifteen minutes at a time are quite sufficient, and the patient should move herself." During my seven years as Master one death was certified as due to pulmonary embolus. The patient died seven hours after delivery, which was complicated by manual removal and post-partum haemorrhage; the uterus was plugged but the bleeding was not controlled.

Appreciating the fact that mobility was beneficial in the morbid puerperium, and prophylactic against complications after normal confinements, it was a short step to the adoption of the same principles in the after-treatment of obstetric operations, such as pubiotomy, Caesarean section, and suture of the perineum. In my first report, dealing with pubiotomy I say, ". . . the belt was discarded on the fourth day and the patient allowed out of bed on the sixth day"; while in my third report I say, ". . . the patients are not bound up in any kind of belt, but are encouraged to move and are able to walk perfectly in 10 to 12 days." Patients who had undergone Caesarean section sat up freely, and laceration of the perineum was treated as though non-existent. Extension of the principles to the post-operative treatment of all gynaecological cases naturally followed rapidly.

Essentials to Success

In the institution of bodily activity after operation there are no specified or routine exercises to be carried out; these only impress the patients with the fallacy that movement must be carefully controlled and possibly entails risk. The aim is to restore, from the time patients return to consciousness, the natural movement of their bodies as well as of their limbs to

obtain restful positions just as they did before operation, or as they would do if merely confined to bed for some minor ailment, and thus to restore the activity of the trunk muscles. To obtain this there are several essentials, the most important being to gain the confidence of the patient so as to counteract the ingrained fear of doing harm or breaking down the stitches. This will be effected only by the display of absolute confidence on the part of the medical attendant, combined with the assurance that the method is based on practical experience and has been proved to be beneficial; also that the advice may be followed despite what others say or think, or the patient's own knowledge or personal experience of wounds that failed to heal owing to reputedly injudicious actions.

I would like here to state my conviction that no wound that has been efficiently sutured in the first instance can be broken down by any muscular activity. A continuous suture may have been cut while being placed, and a low sepsis or haematoma in the wound may prevent healing from the start; but even meteorism, vomiting, or coughing will not break down a healthy sutured wound, and I think this is borne out by the state of wounds that have to be reopened during the first few days after operation. Advanced age and debility, rather than being contraindications, are reasons for earlier and more insistent adoption of the principles.

Next it is essential that control of the patients should be started from the time they are returned to bed, and that while they are in a semiconscious state they be directed to get into and be retained in positions of complete relaxation and the normal positions of rest. This depends entirely on the nursing staff; it does not call for constant personal attention, but can be carried out in conjunction with the ordinary routine work in the ward. For the first 24 hours it is not enough to be able to say the patient is not complaining; if distorted and twisted positions are adopted the patient must at once be replaced in a position of restful relaxation.

The Method in Practice

To define the whole procedure I shall describe a case after laparotomy. As I am engaged in gynaecology and obstetrics, what I say applies primarily to that branch of surgery; but much of it is applicable to general surgery, and is adopted by my colleagues in hospital, where we work in a common female surgical ward with the same sister and nursing staff, and thus the influence of one patient on another takes effect. I apply exactly the same principles to all cases—abdominal operations, with or without drainage, and vaginal plastic operations. Patients are not kept in bed during the days before operation, the aim being to admit them at most two nights before.

Closing the Abdomen.—The abdominal wound is closed with three continuous sutures of plain catgut. No tension sutures are inserted, and neither do my colleagues use them. The skin is closed with a continuous No. 0 plain catgut suture. Two 4-inch (10-cm.) strips of 1-inch (2.5-cm.) strapping are laid across the incision, and then three or four layers of gauze covering the line of suture. This is covered by a sheet of plaster 5 by 7 in. (12.5 by 17.5 cm.) laid over the abdomen. A band of 3-inch (7.5-cm.) strapping is placed smoothly along the top of the sheet of plaster and running a short way round the flank. The dressing is not moved until the fifth to seventh morning. When the abdomen is drained through the lower angle of the wound a few extra layers of gauze are placed over the tube and the lower edge of the plaster and kept in place with strapping and a split "T" bandage. After vaginal operations no form of tampon or even drain is inserted; the vulva is covered by a pad held with a "T" bandage. I mention these details to emphasize the fact that I take no precautions against rupture of the scar; in fact the suture material used is the least durable type. My objection to tension sutures and clips is that they cause pain in the skin if they receive the least traction or displacement, and this inhibits movement. An abdominal binder is used for only twelve hours while the patient is unconscious and has to be moved; it is merely to prevent the strapping being displaced before adhering firmly.

Position After Operation.—When the patient leaves the table she is put on the trolley in exactly the same position as she will be placed in bed—that is, in complete flexion on her side.

She is lifted into bed lying on one or other side; her hips are pulled well out to the side of the bed, her shoulders are in about the middle line of the bed, her thighs and knees are flexed, the upper knee higher than the lower. Her lower shoulder is slightly posterior to the spine, so that the whole body has a tendency to fall over into a prone position. The arms are flexed in front of the body, and they and the flexed knees prevent pronation. The head is well flexed forward; it rests on a full pillow which is not under the shoulders, and the side of the face lies on the pillow so that the mouth is slightly dependent. The patient is left in this position, and need be only casually watched until the deep anaesthesia begins to pass off.

When it is noticed that she is beginning to move a nurse should stand by, and if the patient vomits she has only to place a hand on the upper shoulder so as to direct any movement forward. All vomitus will be ejected and flow out of the mouth

FIG. 1.—Position of patient when returned to bed. Lateral decubitus; limbs flexed; upper knee flexed and forward.

owing to its dependent position, and thus keep the airways clear; and as the patient returns more to consciousness she instinctively raises her head and shoulders and turns more laterally to aid the act. In due time she will begin to roll over towards her back, and if left alone will end by turning her shoulders but not her hips. She must not be allowed to remain in this twisted position, as it results in painful groups of stiff muscles which are a most productive factor in the subsequent disinclination to move. The nurse should go behind her and tell her distinctly and repeatedly, "Turn over; right over on the other side"; at the same time pushing the hips. When the patient responds the nurse goes round the bed and, telling her to lift her hips out to that side of the bed, assists her in doing so, settles her shoulders and head, draws the pillow in front of the face, thus placing her in the lateral flexed position opposite to that in which she was returned to bed. The patient settles down again to peaceful sleep. This may have to be repeated two or three times in the course of the next few hours, after which she is sufficiently awake not to adopt distorted positions. If she tends to lie flat on her back, she should not be allowed to remain so for long but be told to turn on her side and get comfortable, and she will generally respond and herself assist in being moved. Urination and sedatives will be referred to later.

Day-to-day Progress

First Day.—During the first day little need be done with a patient who is co-operative; she has probably already been out of bed. In the morning she is asked to sit up in bed, and is assisted and shown how to do so properly. She gets into comfortable relaxed positions, moves up on her pillows, or props herself laterally on her elbows to take drinks from her bedside table. She frequently through the day partly sits up, with extra pillows, for short periods, but spends most of the time lying down. She is allowed to move and twist about in bed as much as she likes, and requires nothing further than not to be told, "Don't: you must not do that."

In the case of the apprehensive patient, the fear of doing harm is far more the inhibiting cause than pain. Constant reassurance must be given on this point. When she adopts distorted postures she must be moved out of them and to some extent coerced to assist herself. The primary debility of the patient is not a governing factor but only a limiting factor in the duration of voluntary effort, and many of the most debili-

tated patients are the most co-operative. I recently had a case of profound and continuing uterine haemorrhage needing immediate anaesthesia and control at 9 p.m. Next morning I got the patient to sit up in bed of herself—just up and down again; she felt giddy and her head swam; but she continued to sit up and go down again through the day, and next day got out of

FIG. 2.—First morning after operation for repair of complete laceration of perineum. Patient had been out of bed on the first night.

bed to urinate. A week after operation a blood count showed R.B.C. 1,250,000, Hb 20%; but during that time she was out of bed and even sat up a few times for 15 or 20 minutes in a chair.

Second Day.—With the co-operative patient the regimen is usually well established during the second day; in the majority of instances she has already been out of bed, even if only to stand for half a minute. She is asked to sit up in bed, and if she has not done so or does not do so properly she is shown how. The sister is on duty in hospital and in private homes I visit in the morning; but even in hospital this has often to await my arrival. It is surprising how often it is necessary to teach even the most willing patient. This is usually and is better done on the first day, and should not be deferred beyond the second day. Sitting up should be done in the following way.

All impedimenta are removed; nothing should be left except the head pillows. The bedclothes are turned down to the hips. An arm is put behind and round the patient's shoulders, taking their weight, and she is asked to assist herself to sit up. She invariably has to be told that she must ease the weight of her shoulders on her arms and draw her body upwards in the bed. When partly up she is firmly supported, and told to get her hands on the bed behind her and while straightening her arms to draw her bottom up to her hands. She probably attains a vertical position of the body with the spine extended and rigid and the arms acting as props. She is now told to put her arms out in front of her and to lean forward. She will ultimately do so, and thus allow her whole spine to flex, her shoulders to drop, and will sit easily balanced. She immediately experiences a sense of relief and readily admits it, whether she has had a laparotomy or a vaginal or perineal operation, even though in the case of the last she has just before been saying that the site of operation is too sore to sit upon. The explanation of this is that until a position of body balance with relaxed muscles is attained the recti, and the levator muscles to counterbalance them, are in a state of tension which causes constant painful traction on the wounded tissues even when the patient is lying down. She should remain sitting for a few minutes with her knees partly flexed and

etting her thighs fall into abduction. This position is entirely harmless in either abdominal or perineal operations. She then lies down again, and often needs to be told that in doing this she should put both arms to one or other side and take the weight of her shoulders on them while sliding her buttocks backwards to the opposite side of the bed. Once complete flexion of the spine has been obtained the semiconscious *en-garde* tension of the muscles will pass off and they will remain relaxed and the patient become voluntarily mobile, subsequently sitting up for longer if not interdicted.

Subsequent Days.—From the third day the patient moves about in bed as freely as she wishes, leans out to her side locker, turns on her elbows and side or sits up for meals, and gets out

FIG. 3

FIG. 4

FIG. 3.—Third morning after salpingo-oophorectomy and the breaking-down of chronic abdomino-pelvic adhesions. The patient had been sitting up and took the cup and saucer at arm's length, but leant back as the photograph required a time exposure.

FIG. 4.—Same patient as in Fig. 3. Seventh day: dinner at the common table, with other patients.

of bed to urinate and defaecate. Incidentally, she has been doing the last all along. On the fourth or fifth day she is allowed to sit up for half an hour several times through the day, and does her own toilet sitting up in bed.

During the second week patients are in and out of bed constantly through the day, sit up for an hour or so, and walk about the ward, and towards the end of the week are up most of the day. They go to the lavatory to do their toilet and have baths from the ninth or tenth day. Small failures of skin union do not prevent this.

Patients do not dress fully until the day before leaving hospital—about the fourteenth day. They are carefully instructed, more particularly if they are going to stay with friends, that they are to get up at the ordinary time, wash and partially dress, have their breakfasts preferably out of bed, and attend to their bowels immediately after; then lie down and rest for an hour or so before coming downstairs. They are to remain up for meals, lie down on their beds at least once for a long rest in the afternoon, and go to bed shortly after their last meal. They are advised to move about actively and quickly for short spells, not

FIG. 5.—Eighth day. Sitting: case of radical cure of prolapse. Standing: case of radical cure of prolapse with vaginal hysterectomy. High colpoperineorrhaphy had been done in both.

to crawl. Those who are in the habit of riding bicycles may resume this activity after a month. The essence of management in early convalescence is to obtain active muscle exercise of the whole body all through the day but never to continue beyond the least feeling of fatigue.

Other Aspects of Nursing Care

Post-operative Sedatives.—Sedatives should not be given until the patient is completely round from the anaesthetic and premedication. Complaints of general discomfort are not an indication for sedatives but for the adoption of restful positions or the elimination of distressful ones. When the patient begins to complain of definite pain in the actual site of operation is soon enough for sedatives, and this is usually not earlier than five to eight hours after operation. They may be repeated once or even twice through the first night and for the next couple of nights, but are better omitted during the daytime. After that hypnotics are preferable at night, but should be dropped as soon as possible and the patient persuaded to try to sleep without them.

Urination.—In seven to nine hours—that is, shortly before settling for the night—the patient is asked to pass urine, and is assisted to sit up fully balanced on the bed-pan but preferably to get out of bed to the night-chair, which the majority do. If urination fails, a catheter is passed without further delay. There is always enough urine to void if spasmodic inhibition is not present, and it is much better to use the catheter than allow any degree of over-distension to develop, as this only adds an additional and potent cause of prolonged inability to pass urine. In the early morning, and then four times at regular intervals in the 24 hours, the same procedure is followed until the act is spontaneous, after which there is never any relapse. The catheter is not often needed more than three or four times, and very rarely after the bowels act. I asked the sister specifically about this in connexion with my colleagues' cases, and she replied, "Oh, yes, they nearly all get out to the night-chair the first evening; it saves so much trouble, and the catheter is such a worry when it has to be continued."

Bowel Action.—One ounce (28.4 ml.) of liquid paraffin is given on the second and third days, and the patient tries to have a bowel action on the night-chair immediately after breakfast each day. Five or ten minutes after finishing breakfast is the fixed time for the effort every day. If on the third day there has been no result, but there is evidence of intestinal activity, a small enema is given and evacuated on the night-chair; when there is no sign of intestinal movement a mild laxative, such as one or two pill. alophen, is taken on the third night, and repeated any night after the morning effort has failed. The majority respond to the paraffin with or without the enema, and only occasionally require a laxative. The essential factor is the strict observance of the "immediately after breakfast" time table.

Bed-rests.—No patient is ever returned to bed and placed on a bed-rest, as such a position for an unconscious flaccid patient, or during the first few days for one who is feeling poorly and is debilitated, results in sagging with an excessive and painful lumbar hump which increases immobility. If after the first few days a patient who is active likes to sit up for some time a bed-rest does no harm, but pillows are better as they can be avoided or pushed out of bed when she wishes to lie down.

Pulmonary Embolus

I have never had a death from, nor even symptoms suggestive of, pulmonary embolus after operation. It is difficult to believe that this is merely luck. Admittedly my operative work has been relatively small, but in the past 25 years it includes over 700 hysterectomies and should have given scope for the occurrence of a few cases. In the only three post-mortem specimens I remember seeing, the clot had formed in the pulmonary artery and extended into a branch; its proximal end had become free and been carried into the other branch, thus blocking the bifurcation and affecting a very large area of lung. On the other hand, considerable areas of lung are found infarcted at necropsies on cases that did not at any time show symptoms of embolism and where no clotting is found in the pulmonary vessels; therefore it must be accepted that the embolus travelled from veins distal to the heart. I believe the former is what occurs in practically all fatal cases, and the probability of an embolus large enough to be fatal being transmitted through the heart is negligible. I may be wrong, but it is upon this belief that I have based my treatment.

In 1923 I wrote: "There is no apparent means of anticipating the accident, nor need any measures be taken to prevent it in a normal case. In a septic case it is rather in the nature of pyaemia" (FitzGibbon, 1923b). In 1937 I added: "Embolus occurs most often in cases that exhibit marked debility and maintain a persistent immobile decubitus." There is no condition that entails this, not even severe haemorrhage after the first 24 hours. The immobility promotes coagulation of blood in the vena cava, right heart, and pulmonary arteries, and the clot is dislodged by some simple action. Treatment is essentially by prevention, and this is effected by promoting circulation and speeding up the rate of the blood-flow by active movement; but movement has often to be insisted upon" (FitzGibbon, 1937). I have nothing further to add to what I have already written, nor grounds for modifying my beliefs or the methods I have long practised.

Thrombophlebitis and Thrombosed Veins in Leg

The treatment of venous thrombosis is based on the same views as those regarding the cause of embolus. In 1923 I wrote: "Thrombophlebitis is always due to infection, and treatment is directed towards the causative condition. When the acute stage of the infection is passed massage does good, but movement should be encouraged" (FitzGibbon, 1923b); and in 1937 I said: "Earlier recovery is promoted by allowing the patient to get up and encouraging active use of the limb as soon as the primary pain has passed" (FitzGibbon, 1937). As for thrombosed veins in the limbs I said, "The condition is unimportant; there is no tendency to embolus." The treatment of thrombosis I have adopted all my life I began in 1901 for two cases of post-typhoid thrombosis with fluctuating temperatures that did not improve with rest. I got the men out of bed to sit in chairs, and after a few days they were moved out of doors. Their temperatures settled, and they were then encouraged to stand and walk about; in a few weeks they were able to follow the routine of the convalescent camp.

FIG. 6.—Two cases (in 1901) of post-typhoid thrombosis, with high temperature persisting into the fifth and sixth weeks.

I completely ignore the limb beyond placing a cage over it if the bedclothes inhibit movement, or putting a pad over a painful surface vein; and in 24 hours, when the primary pain, if there has been any, has eased, the patients are got to sit in chairs several times each day, to work the limb and walk about. I have never adopted massage, as the benefit obtained cannot compare with that from active muscular action. I can find records of only two cases delayed in hospital by thrombosis in the legs or thighs, and neither was for longer than ten days.

Conclusion

When I am asked if there are any contraindications to active movement I answer that there are absolutely none. The one essential I demand in all operations is complete haemostasis, obtained by direct ligation of the bleeding-point. If an area is moist, the bleeding-point must be found and ligated before that area is covered; or if it has been closed and oozes it must be

opened up and the bleeding-point found and tied. Bleeding must not be controlled by tampon. I am not a believer in post-operative or secondary deferred shock. There often is a profound post-anaesthetic depression, especially if there is nausea, but this always passes off and does not recur, although it may cause anxiety and call for mild restorative measures; and I like to be able to say with certainty that the depression is not due to continued bleeding or renewed loss of blood consequent upon the recovery of the blood pressure as the effects of anaesthesia pass off.

Figs. 1-5 are taken from photographs of the first four patients operated upon after starting to write the paper.

INABILITY TO WORK IN A TROPICAL CLIMATE

BY

H. J. TRENCHARD, M.B., Ch.B., M.R.C.P.
Wing Commander, R.A.F.O.

This paper is a report on Royal Air Force personnel who were medically boarded during the twelve months October, 1944, to September, 1945, at a station in India and found to require transfer home.

The sources from which patients came to the medical board were (1) the R.A.F. station itself, and (2) a group of Army hospitals in the vicinity in which R.A.F. as well as Army patients were treated. The R.A.F. station had an average strength of approximately 3,000 to 4,000 British airmen, although the numbers varied considerably from week to week, and occasionally reached 5,000. The Army hospitals contained approximately 6,000 beds and were equipped to deal with all types of cases. R.A.F. patients were admitted from the R.A.F. station and from other parts of South-East Asia, particularly the "forward areas"—i.e., Burma and Bengal. The total number of R.A.F. admissions was 2,626, of which 1,359 were from the local units composing the R.A.F. station and 1,267 from other units, mainly in the "forward areas."

Ground staffs were dealt with principally; air-crew personnel usually attended other centres. In the series reported only 22 of the 373 men medically boarded were air-crew personnel. Cases of pulmonary tuberculosis were not boarded at the centre in question; only 4 such cases passed through the hospitals during the period under review.

It must be remembered that invaliding home from South-East Asia did not necessarily mean invaliding from the Service. A considerable number of those found unfit for duty in South-East Asia were regarded as fit for home service. Generally speaking the standard set was that those likely to require over three months' in-patient treatment were recommended for repatriation. Of the 373 men returned to the United Kingdom only 60, of whom 18 had had injuries, were considered to require transfer by hospital ship. The remainder were deemed fit to proceed by normal trooping arrangements, even though some medical treatment might be required *en route*.

The ages of the men varied from 18 to 47, the majority being between 20 and 30 (see Table I). Most of them had been in the

TABLE I.—Age Distribution of Cases Recommended for Transfer to United Kingdom

Age:	18-19	20-24	25-29	30-34	35-39	40-44	45 and Over	Total
Number	2	167	68	60	48	25	3	373

R.A.F. for between 2 and 5 years, although one had only 9 months' service and one had 25 years', their length of service overseas varied from 2 months to 51 months at the time of appearing before the medical board. Table II gives the numbers in each six-monthly period of overseas service for all cases and

length of service in South-East Asia was between 3 and 47 months—average 18 months. It will be seen that many had been able to carry on for some time, but those who required boarding within a year of arrival in India were very poor specimens indeed.

An attempt has been made to discover the precipitating factor in each case, and the results are given in Table IV. It is not

TABLE IV.—Principal Precipitating Factors in 86 Cases of Anxiety Neurosis

"Domestic" stresses	43
Separation from family	8
Family worries, near relations ill, in danger from air raids, in financial difficulties, etc.	13
Quarrel with family	3
Wife unfaithful and pregnant by another man	8
Wife unfaithful	8
Patient responsible for an illegitimate pregnancy	3
"Service" stresses	23
Discomforts of overseas service	19
Active service (stress in action)	2
Flying	2
"Personal" stresses	5
Following injury in an accident	3
Repeated organic illness	1
Worry through being accidental cause of another's death	1
No principal precipitating factor discovered	15

suggested that the individual's constitutional predisposition is not primarily responsible for the condition. (In 44 cases a history of neurotic traits in childhood or adolescence was admitted.) When, however, the history showed the presence of a stress connected with the onset of symptoms, this was regarded as the precipitating factor. The most important precipitating factors appear to be family worries and overseas service. The importance of harmonious relations with and reassuring news from home in its effect on the morale of the Serviceman overseas can thus be seen. In addition, tropical service can be particularly difficult, especially for other ranks, with anxiety concerning tropical diseases, the effects of heat, and the dislike of the inhabitants and their customs and habits. The symptoms complained of by those with anxiety neurosis were nervousness, headache, inability to concentrate, and feeling depressed. In 6 suicide was threatened, and a few had symptoms of insomnia, dyspepsia, and palpitation.

Other Psychological Disorders

There were 33 cases diagnosed as hysteria. The maximum length of service was 8 years 6 months and the minimum 1 year and 5 months. The length of service in South-East Asia varied between 4 and 40 months. The predisposing cause in all cases appeared to be a subconscious desire to return home. In the majority the symptoms were of a sensory type. Details are given in Table V.

TABLE V.—Principal Symptoms in 33 Cases of Hysteria

aches, depression, and	14	Somnambulism	1
izziness	6	Fugues	2
digestion or abdominal pain	4	Stammer	2
ains or tingling in limbs	1	Hysterical gait, with stammer	1
Skin rash	1	Weakness of shoulder	1
"Blackouts"	1		

The 2 men with obsessional neurosis had been nervous and worrying, though conscientious, individuals all their life. They were overcome by the responsibilities of their duties. One was an officer, the other an armourer worrying lest he let down his pilot.

The psychotics consisted of 2 cases of melancholia, 5 of simple schizophrenia, 5 of hebephrenic schizophrenia, 1 of the katatonic type, and 2 of the paranoid variety. They are chiefly remarkable for the length of service—over 2 years 9 months in all cases, and 5 years in most. They are divided into two groups on overseas service; 8 required invaliding within 12 months, while 7 carried on for over 2 years.

Among the 11 cases of psychopathic personality were 2 practising passive homosexuals. The remainder consisted of 5 men whose Service careers showed that they had been slovenly and inefficient no matter what duties, however simple, they were given to do; 2 who showed depression and lack of control of their bad tempers; and 2, diagnosed as psychopathic personality (emotional abnormality type), whose presenting symptoms were

nervousness and a stammer. On the whole these cases are chiefly remarkable for the length of time that the patients continued to serve before admission to hospital and invaliding became necessary.

Summary

The causes during the year October, 1944, to September, 1945, of invaliding from South-East Asia of 373 members of the Royal Air Force are reviewed.

The principal causes were found to be psychiatric, anxiety neurosis being the most frequent.

Domestic worries were of special importance as precipitating factors in the cases of anxiety neurosis. The stress of Service life in a tropical climate was the next most important.

A large number of the "psychiatric" patients had continued to serve for quite long periods before repatriation became necessary.

Injuries were an important cause of invaliding, but enemy action accounted for very few of them.

The 5 patients with chronic suppurative otitis media had all served overseas for more than a year before being boarded.

Skin diseases were an important cause of invaliding, especially soon after arrival in South-East Asia.

Malaria was responsible for very few cases, probably due to the use of mepacrine suppressive-therapy.

Chronic diarrhoea, amoebiasis, and sprue were important causes of invaliding. The majority of cases originated in the "forward areas," where the living conditions were poorer.

THE FAECES IN SPRUE

BY

D. A. K. BLACK, M.D. P. FOURMAN, M.D.

AND

P. TRINDER

During an investigation on tropical sprue carried out in Poona by the fat-balance technique we have had the opportunity of observing more than 500 four-day specimens of sprue stools. The quantitative fat-balance results have been discussed elsewhere, but routine examination of this large number of specimens has brought to our notice certain characteristics of the sprue stool which have received comparatively little attention but which have an important bearing on diagnosis. The purpose of this paper is to describe these findings, and to discuss their significance in relation to the detection of steatorrhoea.

Material and Methods

All the stool specimens came from patients who were shown by fat-balance experiment to have an impaired absorption of fat. The patients had all lost weight significantly, and many of them showed tongue signs and complained of flatulence, and of "diarrhoea" in a general sense. Their illness had in all cases appeared while they were on tropical service. They were all on a diet of known fat content—either 66 g. or 96 g. of fat per day—and stools were collected quantitatively over four-day periods in large tins. Formalin was necessary as a preservative to prevent growth of moulds; 100 ml. of 5% formalin was used for each period. The stools were weighed in bulk, and aliquots dried for estimation of total fat, fatty acids, and soaps. The water content and non-fat dry residue were calculated from weighings as described below. Indicator strips were used for the approximate determination of pH.

General Appearance of Sprue Stools

The stools in sprue are usually described as pale, bulky, and fatty; when patients are on a controlled diet of moderate fat content most of their stools conform well to this description. They are well formed, and the cut surface has a distinct sheen from the presence of fatty acid crystals. Such stools are easy to recognize, and at once raise the suspicion of sprue. Two important deviations from the "typical sprue stool" need special mention, as they are common, and may be misleading if undue reliance is placed on the general appearance of the stool.

(1) Many stools of high fat content, as shown by analysis, are well pigmented and not unduly bulky; in an earlier series no less than half the stools with a fat content of more than 25% of the

dry weight were found to be well coloured (Black and Fourman, 1945). Pallor in the sprue stool is generally attributed to the reduction of stercobilin to stercobilinogen, which is colourless. The ultimate cause of this reduction is not known, but it seems not to be closely related to the fat content of the stools; those containing similar amounts of fat may be very differently coloured, and even in a single unmixed stool part may be pale and part pigmented. On exposure to light and air pale stools darken in colour. A contributory cause of pallor in the sprue stool may be simple dilution of pigment by the increased bulk of fat.

(2) Many patients with sprue give a history of one or more attacks of watery diarrhoea, which may occasion considerable loss of water and salt (Black, 1946); in such a phase the diagnosis of "clinical dysentery" is often made. In the tropics some of these diarrhoeic episodes may represent an actual intercurrent dysenteric infection; but the characteristic exudate of bacillary dysentery is found only seldom. In spite of this, sulphaguanidine has a therapeutic effect in this type of diarrhoea; it is possible that sulphonamide-sensitive organisms which are normally harmless commensals may become pathogenic in an abnormal alimentary tract. Not only sulphaguanidine, but also parenteral liver extract in adequate dosage, have been found to abort diarrhoea, suggesting that the resistance of the bowel wall to infection may be concerned in this type of diarrhoea, as well as the character of the intestinal flora.

Fats in the Sprue Stool

All the patients in the series were excreting in the stools an amount of fat corresponding to more than 10% of the dietary fat. It occasionally happened that the fat content of the dry stool was less than 25%—i.e., within the generally accepted normal limit; but the total daily fat excretion was more than 10 g. The fat content of any given stool obviously depends not only on the amount of fat in the diet but also on the "high residue" or "low residue" character of the diet, which may be quite independent of its fat content. The effect of the fat content of the diet was well illustrated by two patients with severe sprue, whose stools became normal when they were put on a diet containing less than 10 g. of fat per day.

Considerable attention has been paid in the past to the degree of "splitting" of the fat in the sprue stool; it has been found that the ratio of split to unsplit fat usually exceeds the normal ratio of 3 or 4 to 1, although occasional stools have been found to contain a larger amount of unsplit fat. The fact that the split fat in the sprue stool forms a higher proportion of the total fat than in normal stools has sometimes been taken to imply a defect in the absorption of split as opposed to unsplit fat; but this neglects the possibility of lipase action in the colon, or in the interval between passage of the stool and analysis. Bloor (1943) states that normal stools are capable of partially splitting neutral fat which is added to them; we have found that this property is shared by the sprue stool, and is in fact present in higher degree than in the normal stool, probably because of the emulsifying action of the large amount of soap in the sprue stool. The addition of sulphathiazole and penicillin did not inhibit the splitting of margarine by a number of sprue stools, so the lipolysis is probably not bacterial; saturated copper sulphate added in a proportion of 5% partly inhibited splitting. In view of the strong lipolytic activity of sprue stools *in vitro*, it does not seem justifiable to draw conclusions as to the relative absorption of split and unsplit fat from the composition of the stools. The high proportion of split fat in the sprue stool is best explained on the basis that unsaponifiable fat is the same in normals and in sprue patients, but the amount of saponifiable fat is much increased in sprue.

We have found that a high proportion of the fat in the sprue stool is present in the form of soaps, in spite of the fact that nearly all the stools were acid in reaction. Table I shows the

TABLE I.—Relationship between Proportion of Split Fat in the Dry Stool and of Split Fat found in the Form of Soap

Split Fat (% of dry wt.)	No. of Stools with Soap Split Fat of:			Total No. of Stools
	<60%	60-80%	>80%	
20-40	5	11	10	26
40-60	1	14	5	20

percentage of the split fat occurring as soaps, grouped in relation to the total percentage of split fat in 45 stools from ten

patients with sprue. The proportion of split fat present as soaps was over 60% in all but six stools. It can be seen from the table that a high proportion of the fat present in stools is in the soap form, irrespective of whether their total fat content is high or low; it follows that fixation of electrolytes in the form of soaps will increase as the total fat content of the stools increases. A considerable part of the soap in the sprue stool is insoluble both in water and in ether, and on analysis is found to contain calcium. The rest of the soap is water-soluble, and we found that the stools which contained most soap were also the most alkaline in reaction (Table II).

TABLE II.—Stools Grouped according to pH and Split Fat Percentage (The figures represent the number of stools in each category)

Split Fat (% of dry stool)	pH 6.2	pH 6.2-	pH 6.6-	pH 7.0-	Total No. of Stools
<30	11	11	12	6	40
>30	5	6	17	23	51
Total	16	17	29	29	91

pH is higher in the more fatty stools; χ^2 13.36, $P < 0.01$

The reaction of 91 stools, not treated with formalin, ranged from pH 5.8 to pH 7.4, the average being 6.7. Table II shows the pH values grouped in relation to the percentage of split fat in the dried stool; the pH is significantly higher in the more fatty stools, which contain the greatest amount of soap. These data on soap content and pH suggest that the well-known irritant character of very fatty stools is due not to excessive acidity but to a high content of soluble soaps. The practice of giving calcium salts to check diarrhoea has some theoretical justification in that it increases the proportion of insoluble soaps at the expense of the irritant soluble soaps.

Non-fat Dry Residue

When the total fat in a stool is subtracted from the total dry weight the amount of dry stool other than the fat (N.F.D.R.) is obtained. This is largely composed of bacteria, but it also contains unabsorbed food residues from dietary constituents other than fat. On a controlled diet the N.F.D.R. should remain constant, provided there are no changes either in the bacterial flora or in the absorption of substances other than fat. It was found, however, that after treatment by liver and yeast extract many, but not all, sprue patients showed a fall in the N.F.D.R. as their stools became less fatty. Our data do not indicate whether this fall in N.F.D.R. was caused by improved absorption of non-fatty substances or by there being fewer bacteria in the stools. From a practical point of view this fall in N.F.D.R. is important, for if percentage fat estimations are used to follow progress a real improvement in fat absorption may be masked by a concomitant fall in the N.F.D.R., the percentage fat in the dried stool remaining the same although the total fat excretion has fallen.

Water Content of Stools

With gross variations in steatorrhoea such as occur with treatment in sprue, a fair measure of the water content of the stool cannot be obtained simply from the ratio of dry to wet stool weight, for the fatty part of the stool is not wetted. The "percentage water content" used is therefore derived from (wet wt. of stool-fat) and (dry wt. of stool-fat). Table III shows the average figures for 66 stools taken at different times

TABLE III.—Relationship between Fat and Water Content of Stools

Fat (% of dry wt.)	Mean Water Content (% of non-fat wet wt.)	Standard Deviation of Mean
<30	76.9	±6.45
30-40	79.95	±4.19
40-50	81.5	±6.44

The differences between the means are significant; $P < 0.02$

from eleven patients with sprue and grouped according to their percentage fat content. Although the series was limited to formed stools, the stools of higher fat content have also a higher percentage of water. As pointed out above, many patients with sprue have a higher non-fat dry residue when

steatorrhoea is gross, so that the figures just given minimize rather than exaggerate the total amount of water lost in the more fatty stools.

Discussion

The diagnosis of sprue very often depends largely on the demonstration of steatorrhoea, for sprue may closely resemble other conditions as diverse as pernicious anaemia, pellagra, and the dysenteric disorders, or may even present with no other symptom than loss of weight. In the majority of severe cases of sprue the percentage of fat in the dried stool is unequivocally raised—upwards of 30% ; but diagnostic difficulty seldom arises in the typical severe case. In patients with mild or atypical sprue, however, the percentage fat content of the dried stool may be within normal limits, especially if the patient is not taking much fat in his diet ; many patients with early sprue have learnt to avoid fatty foods. In order to demonstrate steatorrhoea in such patients it is necessary to put them on a diet of limited fat content (90–100 g. per day), and to collect the total stool for a period of at least 24 hours, and preferably four days, demarcated by carmine markers. The total amount of fat excreted should not exceed 10 g. per day in a normal person. In the absence of facilities for collecting and weighing stools, a percentage estimation of the fat in a mixed 24-hour stool has more value than percentage fat estimation on an isolated stool specimen, for we have repeatedly observed that individual stools from patients with steatorrhoea may be normal both in appearance and in fat content. If a percentage estimation of fat is to be used a "high residue" diet is inadmissible, for minor degrees of steatorrhoea will not be apparent if the non-fat dry residue is also high. For scientific work on fat excretion longer periods are necessary, as the variation between successive short periods is considerable ; twelve days probably represents a minimum for this type of work, but is obviously impracticable in routine diagnosis, for which a four-day period is a suitable compromise between the desirable and the attainable.

Summary

Although the majority of stools from patients with tropical sprue are pale, bulky, and formed, two other types of stool are found often enough to cause difficulty in diagnosis. These types are a well-pigmented formed stool, which is found to be fatty only on actual analysis ; and copious watery stools.

A high proportion of the fat in the sprue stool is in the form of soaps, both soluble and insoluble ; the irritant character of very fatty stools is due to the presence of soluble soaps, and not to excessive acidity.

For the detection of minor degrees of steatorrhoea it is necessary to give a diet containing about 100 g. of fat per day, and to collect the stools over a known period ; percentage fat estimation alone may be misleading, because of variation in fat content from stool to stool, and also because a high-residue diet will lead to low values for the fat percentage in the dried stool.

We are grateful to the Director of Medical Services in India for permission to publish this work, which formed part of a G.H.Q.(I.) investigation on tropical sprue.

A new scheme for the training of nursery workers in Scotland is being devised, and details have been sent out to local authorities and education authorities in a circular issued jointly by the Department of Health and the Scottish Education Department. This says that the Secretary of State (Mr. Joseph Westwood) has considered the necessity of ensuring an adequate flow of properly trained nursery workers in nurseries, nursery schools, and children's homes of all kinds. There is likely to be an increasing need for such workers and there should be uniformity in their training. Mr. Westwood's view is that a training course for such workers would also form a useful preliminary to further training should the student, for example, wish to proceed to child welfare work or to hospital nursing. The training in Scotland has, up to now, consisted almost entirely of that sponsored by the National Society of Children's Nurseries, and great credit is due to that society for its pioneer work. The time has come, however, to institute, in place of existing arrangements, a Scottish nursery nurse's certificate to be awarded to girls in nurseries of all types who have followed a specially designed course of practical and theoretical training and have passed an examination conducted by a Nursery Nurses Examination Board. Such a Board has accordingly been set up.

Medical Memoranda

Unilateral Micromastia associated with Abnormalities of Musculature of Chest Wall on Same Side

Although this condition is referred to in most textbooks surgery, only a few cases have been recorded in the literature. It must be distinguished from amastia, in which there is complete absence of breast tissue, although "a rudimentary nipple is usually present."

CASE REPORT

A married woman aged 37 was admitted to the City Mental Hospital, Nottingham, as a voluntary patient in November, 1945, suffering from reactive depression. Physical examination revealed that her right breast, nipple, and areola were in an undeveloped condition (Fig. 1). A very small amount of breast tissue was palpable, and there were a few hairs arising from the periphery of the areola. The left breast, nipple, and areola were normal in appearance. The anterior fold of the right axilla ran slightly upwards in the direction of the right sterno-clavicular joint, instead of inclining downwards in the usual way (Fig. 1). This was partly due to the undeveloped condition of the right breast but chiefly to the complete absence of the sterno-costal part of the right pectoralis major. The anterior fold of the axilla thus followed the line of the lower border of the clavicular part of the muscle. The pectoralis minor was present but was very poorly developed. The lateral aspect of the right side of the chest there was a shallow depression, with its centre approximately at the level of the 5th

FIG. 1

FIG. 2

rib. Over this area the chest wall was very thin, the percussion note being hyper-resonant. This was due to the apparently complete absence of the serratus anterior, as a result of which there was pronounced winging of the scapula on raising the arms horizontally in front of the body (Fig. 2). In addition, the latissimus dorsi on the right side was poorly developed. Finally, there was a prominent muscle belly extending from the region of the transverse processes of the fifth and sixth thoracic vertebrae to the medial border of the scapula (midway between the root of the spine and the inferior angle), the direction of its fibres being upwards and outwards (Fig. 2). It was apparently an anomalous lower part of the right trapezius. Its action was to pull the scapula forwards, medially, and downwards. No other abnormalities of the muscles of the chest wall were discovered. With the arms hanging loosely by the sides, the right scapula was displaced upwards and medially and rotated clockwise (i.e., when viewed from behind), this being due to the compensatory action of the intact muscles.

There were two other points of interest. First, the right breast did not lactate after either of the patient's two pregnancies, although it enlarged a little. (The left breast did lactate, but not adequately.) The second point concerned the patient's handedness. She was left-handed in using scissors, in picking up heavy objects, in ironing, and in eating with a spoon ; right-handed in writing and in eating with a knife and fork ; and ambidextrous as regards sewing. In this connexion it may be mentioned that her father was left-handed in all things and her younger son writes with his left hand. The muscles of her right arm were slightly smaller and slightly weaker than the corresponding ones of her left arm.

E. R. BANNER, M.B., Ch.B.,

City Mental Hospital, Nottingham.

Temporary Assistant Medical Officer.

The Belgrave Hospital for Children, Clapham Road, London, admitted 1,351 children to its wards last year, and 8,000 attended the out-patient department—a large increase in numbers. Arrangements are going forward for the amalgamation of the Belgrave Hospital and the Victoria Hospital for Children.

Reviews

ESSAYS ON HUMAN EVOLUTION

Essays on Human Evolution. By Sir Arthur Keith. (Pp. 224. 15s.) London: Watts and Co.

Is science now in a position to formulate the principles of ethics as Dr. C. H. Waddington recently maintained? Sir Arthur Keith answers this definitely in the negative. It may be recalled that in an earlier essay Sir Arthur drew attention to two strong and opposing forces in evolution, one the insistent demand for the enlargement of the unit; the other, the group consciousness of a community which restricts and isolates. The first tendency makes for internationalism, the second, for nationalism. In this volume he has considerably accentuated this distinction and, indeed, to some extent has modified his own position. For him now the evolutionary process is entirely severed from any ethical considerations whatever, carrying on its development in utter ruthlessness. Any ethical principles that come into being are due to developments in the consciousness of the community group. The author points out, however, that in all human institutions we find both tendencies at work: the "cosmical" and the ethical. In general we apply the cosmical to our enemies, the ethical to our own community. Nevertheless, if the interests of the group are threatened there is an immediate reversion to the cosmical attitude. In other words, we are all "bicodal" and any attempt to be logically entirely "unicodal" ends in disaster.

Naturally he discusses this particularly in relation to war. To adopt the unicodal system in wartime is to be overthrown, and much of civilization would disappear in the process. Incidentally, he rather withdraws from his much-criticized metaphor of "the pruning-hook of war." He points out, however in an interesting way, that the invader who follows the inhuman evolutionary path suffers the fate of absorption by the defeated. Where are now the Goths? They have been completely assimilated by the races they tried to destroy. There is much food for thought and also for controversy in these pages. Thus, to regard the Athenians as evolutionary failures because they subsequently sacrificed themselves on the altar of civilization seems to us to be misleading, for throughout all the centuries fresh inspiration has been repeatedly drawn from them. Can this be accounted failure?

By this book Sir Arthur Keith, who has already done such great service in the fields of anthropology, archaeology, and evolution, has increased our debt to him. W. L-B

NEUROPATHY AND DEFICIENCIES OF B VITAMINS

Avitaminosis y Sistema Nervioso. By F. Grande and M. Peraita. (Pp. 244. No price given.) Madrid-Barcelona: Editorial "Miguel Servet."

The Spanish Civil War produced nutritional deficiencies characterized by dermatological, mental, and neurological disorders. An extensive study of these conditions has been undertaken by Grande and Peraita and reported in their monograph. Out of 300 patients, approximately 100 suffered from serious pellagrous psychosis, and 100 showed characteristic pellagrous skin lesions. Only the remaining 100 patients, having distinct neurological disorders without cutaneous lesions, were systematically investigated. The majority of these cases were women of 40 years or above. The most frequent symptoms were paraesthesia of various kinds such as acroparaesthesia, pain dysaesthesia, fulgurating and lancinating pain, and paraesthetic sensations of wetness. Neurasthenic symptoms were present in 84%, while glossitis, alterations in gait, causalgic symptoms, and a feeling of cold were less frequent (54%). Optical retrobulbar neuritis, visual pseudoperceptions, disorders of micturition, intestinal disturbances, achromotrichia, trophic disorders of the skin, erythema pernio, hypohidrosis were less frequent.

The symptoms mentioned above are described in great detail. The extreme persistence of these sensations is stressed. The description recalls identical reports of Spillane and Scott, and Spillane from the Middle and Far East (*Lancet*, 1945, 2, 261, 317). The majority of patients had either normal or increased

ankle-jerks and knee-jerks. Pathological pyramidal reflexes and diminished responses were rarely observed. The symptoms were due to disorders in the sensory and neuro-vasomotor system of central or peripheral type. "Cold" paraesthesia was connected with a drop in skin temperature, established by careful thermo-electric measurements. The neurasthenic syndrome seemed to be connected with changes in the mesodiencephalon. The various symptoms could be grouped into distinct categories according to their intensity and localization, as has already been mentioned in a previous review of Peraita's work in our issue of Feb. 26, 1944. A careful comparison has been made between the pellagrous neuropathies and neuropathies in vitamin B₁ deficiency. The total absence of pareses, paralyses, or typical trophic disorders of the beriberi type was remarkable, and the authors conclude that the symptoms observed are different from those found in vitamin B₁ deficiency. Limited therapeutic trials with the B vitamins available did not establish quite clearly whether either nicotinic acid or vitamin B₁ was beneficial. Yeast preparations in amounts of 90-100 g. daily relieved the majority of the symptoms to a remarkable degree.

The connexion between neuropathies and B vitamins deserves the attention of nutritionists and biochemists. As Prof. Peters pointed out at a recent meeting of the Nutrition Society, the role of B vitamins in the metabolism of nervous tissue may prove a fruitful line of future research.

CAUSATION OF APPENDICITIS

The Causation of Appendicitis. By A. Rendle Short, M.D., B.S., F.R.C.S. (Pp. 79. 10s.) Bristol: John Wright and Sons. 1946.

One of the commonest questions put to the surgeon dealing with a case of appendicitis by both patients and relatives is, "What is it due to?" Many attempts have been made to provide a satisfactory scientific answer; for instance, over a quarter of a century ago Mr. Rendle Short published his observations on the subject; he has now elaborated his thesis and brought his statistics up to date in a small book. In brief he believes that there was a real and great increase in the incidence of appendicitis between 1895 and 1905 and that of all the numerous changes in the life of the community which occurred at this time, the most significant was the diminution, either relative or absolute, in the consumption of cellulose. It is the roughage value of the cellulose and not any particular chemical virtue with which he is concerned.

Whether one agrees or disagrees with the conclusions reached by the author, it must be allowed that he does not let any fanaticism warp his arguments, and he readily acknowledges that some of the statistics he produces do not support his contention or are capable of other interpretations. We were interested to find him quoting that inimitable master of scornful travesty, the late Dr. Charles Mercier, who put forward the theory that appendicitis was due to the abandonment of wig-wearing because there were no cases recorded from the days when wigs came in to the date when, except for judges, barristers, and Victorian bishops, they went out—and "who ever heard of appendicitis in a wigged bishop?" A clever skit on a type of specious deduction too frequently heard. But the fact that Mr. Rendle Short puts in this quotation shows that he appreciates, and steers clear of, such pitfalls. It would be idle to pretend that the reader will not be roused to criticism of many of the author's deductions—we found ourselves unconvinced by his conclusions—but therein lies the attraction of the book, which we can recommend unhesitatingly to all interested in the aetiology of this common disease—and who in medicine is not?

HYPNOANALYSIS

Hypnoanalysis. By Lewis R. Wolberg, M.D., lecturer in psychiatry, New York Medical College. Foreword by A. Kardiner, M.D. (Pp. 342; 21s.) London: William Heinemann Medical Books. 1946.

Since the efflorescence of the Nancy School hypnotism has gradually receded in popularity among psychotherapists. Some of the more credulous of the public who enjoy the idea of magic still hanker after it, but it has come to be regarded as less scientific and therefore less worthy than the various analytic procedures. Recently, in the efforts to discover short cuts in analysis which will allow psychotherapy to be used in a greater number of patients, several workers have been again turning

their attention to hypnosis. The present work is a careful and honest effort to assess the advantages and limitations of the use of this method in conjunction with analysis. Its chief value lies in the uncovering of buried memories, but some of these which are very deeply repressed do not emerge even in the deepest hypnosis. The integration of these memories in the conscious personality is not always easy, but the author thinks that they can be reintegrated by such methods as crystal gazing in the more conscious state. The transference state is intensified by this method and (according to the author) can be more clearly understood than in the process of waking analysis. Hypnoanalytic procedures are well described and the whole theoretic considerations of the book are illustrated and built round the detailed description of the successful treatment of a schizophrenic personality.

This is a relatively new method of therapy, though founded on old theories and practices, and it certainly merits the study of those who wish to extend their therapeutic armamentarium and find new short cuts in their analytic technique.

ANATOMY OF THE EXTREMITIES

The Extremities. By Daniel P. Quiring, Ph.D., Beatrice A. Boyle, Erna L. Boroush, M.A., and Bernardine Lufkin, A.B. (Pp. 117; 106 engravings; 14s.) London: Henry Kimpton. 1946.

This book marks a new departure in manuals of topographical applied anatomy. Its main purpose is to show diagrammatically the "motor points" of the muscles of the upper and lower limbs. The location of these points has been determined by observations on the response of muscles to electrical stimulation in a series of normal subjects. The work has been carried out by Prof. D. P. Quiring, Beatrice A. Boyle, Erna L. Boroush, and Bernardine Lufkin, in the Anatomy Division of the Cleveland Clinic, Ohio. The diagrams, based on original dissections, have legends giving the principal attachments, functions, nerve and arterial supply of each muscle. The muscles and skeletal parts are shown in outline, while the nerves and arteries supplying each muscle are shown at their point of entry into the muscle, and for a short distance inside and outside the muscle. This is of importance, because the position of the motor point usually corresponds fairly closely to the point of entry of the nerve into the muscle. Difficulties have naturally arisen in representing muscles in simple outline upon the flat surface of the paper, owing to certain muscles following a curved surface, such as the thoracic wall or shoulder—e.g., the serratus anterior and deltoid muscle. Attempts have been made to overcome these difficulties, with a certain measure of success, but it is obvious in the diagram representing the deltoid muscle that the outline of the shoulder viewed from behind has been utilized to indicate the outline of the muscle in front in place of the true anterior border, which otherwise could only have been represented in its proper position by an interrupted line.

The book as a whole clearly fulfils its purpose of indicating the position of the motor points of each muscle for use in the diagnosis and electrical treatment of muscular defects of the upper and lower limbs, and can be recommended as a reliable and handy work of reference.

Notes on Books

Diseases of the Breast, by C. F. GESCHICKTER (J. B. Lippincott Company; 72s.), covers the whole of the pathology and surgery of the breast from the point of view of the pathologist, and as such we believe it to be unique. The detailed description of the development of the breast itself and of the many pathological conditions which may arise is superb and could only be achieved by a life-time devoted to the subject. The surgical descriptions are adequate but have not quite the same character. A considerable part of the book is devoted to experimental work on the rat, and though the work is no doubt of great value its application to human disease must remain doubtful. To the surgeon who would make himself familiar with the whole complex subject of the pathology of breast tumours the volume would be invaluable.

Your Child—Your Future! by CHARLOTTE and EMIL LEITNER is published by Victor Gollancz, Ltd., at 1s. 6d. The authors have been working in the Cheltenham child guidance clinic and their little book may very well be recommended to parents ignorant of psychology and modern child guidance methods. It has the great merits of brevity, clarity, and cheapness. It is reasonably safe to say that there is nothing in it which should not

have been written, and the authors deserve credit for treating their subject entirely from the preventive point of view. Thus parents may learn from this book how to treat the child while it is normal, and it will not encourage them to think they know what to do when the child becomes abnormal. Many of them will need much more detail than is given here, and there are plenty of books to give them that; but this publication is so simple and short that the parent who says that he or she has not the time, inclination, or ability to read anything in the least abstruse can hardly complain if asked to study these 58 pages of good-sized type.

Public Health in the U.S.S.R., by Prof. NIKOLAI SEMASHKO, is one of the Soviet News Booklets published from 630, Grand Buildings, Trafalgar Square, London, W.C.2., price 1s. The author was Peoples Commissar of Health from 1918 to 1930 and is a member of the Medical Council of the Health Ministry. The constitution of the U.S.S.R. gives every citizen the right to maintenance in old age and in sickness or loss of capacity for work, and the right to free medical attention. Effect is given to this by the widespread development of health resorts, holiday homes, sanatoria, factory clinics, polyclinics, hospitals, mother and child clinics, etc. Prof. Semashko says that the Soviet health service is now rapidly repairing the damage done by the war and planning its further development.

The new edition for 1946 of the *Directory of Guy's Men* is the first to appear since 1941. It is published at 5s. from the Gazette Office, Guy's Hospital, London Bridge, S.E.1. The first part contains the names, qualifications, and addresses of medical men, and the second gives particulars of those who are graduates and licentiates in dental surgery. There is also a bibliography of published writings by members of the staff of Guy's Hospital between July, 1940, and September, 1945.

Preparations and Appliances

A NEW PENICILLIN INHALER

Dr. L. CAPPER, late Resident Medical Officer, London Chest Hospital, writes:

The penicillin inhaler shown below has been in use at the London Chest Hospital for some months past. The results obtained with it have been satisfactory both clinically and bacteriologically, and it would appear that an effective concentration of penicillin can be maintained in the sputum by its use for far longer periods than has been the case with other inhalers which have been subjected to similar clinical tests. A clinical report of the cases which have been treated is to be published. The inhaler was made for us by the British Oxygen Co.

Oxygen at the rate of 6 litres per minute enters the inhaler at (F) from a cylinder fitted with the usual pressure gauge (B) and flowmeter (E). At (M) is inserted a Y-shaped glass connector which has one of its limbs open to the air. Thus the patient, by occluding the open limb with his finger during inspiration only, ensures that penicillin is not atomized during expiration. (H) is a standard penicillin bottle in which the requisite dose of penicillin dissolved in normal saline is placed and through its cap a 3-in. needle (G) is inserted. The needle fits on to a record-fitting jet (K). The inner aperture of this is of controlled size and through it the aerosol escapes into the face-mask (L). (I) is an expiratory valve and (J) a rebreathing bag so that the patient can keep the mask on his face throughout the whole duration of the inhalation.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 21 1946

TRANSFUSION JAUNDICE

The possibility that certain apparently normal individuals might be carrying a hepatitis-producing agent in their blood was first reported in England in 1937 from two separate sources. In one instance the suspected blood product was measles convalescent serum,¹ and in the other yellow fever vaccine containing normal human serum.² These incidents unfortunately attracted little serious attention from the majority of medical men because so many had used human blood or blood products with apparently no resulting hepatitis, and the hepatitis from yellow fever vaccine was confused with the fact that the yellow fever virus itself affects the liver. The usually long interval of 60 to 150 days between inoculation and the onset of hepatitis also served to mask the possible relation between the two events, especially if the patient had moved to another locality in the interval.

The significance of these earlier observations was revealed when two large "epidemics" of jaundice followed the inoculation into Brazilians³ in 1940 and American troops⁴ in 1942 of certain batches of yellow fever vaccine containing human serum. These were followed in 1942 by "outbreaks" of jaundice in England among individuals who had received mumps convalescent plasma from apparently healthy donors,⁵ recipients of yellow fever vaccine containing pooled normal human serum from blood transfusion centres,⁶ and surgical patients transfused with pooled normal human serum.⁷ All these incidents had been related to pooled serum or plasma, but in 1943 Beeson⁸ in the U.S.A. reported 4 possible cases of the disease in individuals who had been transfused with whole blood. Further suspicious cases of this nature were recorded in England. In spite of this convincing evidence those attacking this problem found it difficult to impress the majority of the profession with its potential seriousness. This was partly due to the failure under air-raid and battle conditions to record on the case history the identifying number of the blood or blood products used. Thus, though suspicious individual cases were identified, it was impossible to relate them to a single source, especially when (epidemic) infective hepatitis was present in the same region. However, experimental work by MacCallum and Bauer,⁹ supported by observations of Bradley and his co-

workers,⁹ proved beyond doubt that certain batches of pooled human serum collected at blood transfusion depots may carry a hepatitis-producing agent of unknown origin. The part which healthy "carriers" play in the dissemination of this disease is not known, but the agent of homologous serum hepatitis has been found circulating in the blood 34 days after subcutaneous inoculation and 60 days before jaundice,¹⁰ and the agent of infective hepatitis has been found 3 days before the onset of symptoms.¹¹ Signs of liver damage have been found in symptomless contacts in an epidemic of infective hepatitis in an institution. Thus there would be ample opportunity for either of these agents to be introduced unknowingly from an apparently healthy donor into a supposedly normal pool of serum.

The position with regard to serum is clearer than it is with regard to hepatitis after transfusion with whole blood, but the conditions accompanying the latter tend to minimize greatly the possibility of such an occurrence. In a pool of serum the icterogenic agent present in one serum may survive pooling with 499 others to provide an icterogenic pool which may be injected into 500 recipients. By contrast a single bottle of whole blood will be used for only one recipient, who may not be susceptible to attack by the agent. In an attempt to find out the effect of the use of single donors of serum Loutit and Maunsell¹² recently injected each of 99 individual sera into an average of six normal recipients. No cases of homologous serum hepatitis were detected.

Though there had been sufficient reports to prove the existence of transfusion jaundice its general incidence was unknown. In 1944 Dr. Janet Vaughan and her colleagues at the North-West London Blood Supply Depot began an investigation, described elsewhere in this issue, to determine the incidence of homologous serum jaundice among the recipients of the 400 different pools of serum and plasma and 3,468 bottles of whole blood provided by their depot. Questionnaires were sent to recipients 5 months after their transfusion. There were 77 cases of jaundice among the 1,054 recipients of serum or plasma surviving and traceable 5 months after transfusion—an incidence of 7.3%. There were no deaths from acute necrosis of the liver among the 77 cases, nor were there any records of those traceable but not surviving the 5 months, having died from this disease. The icterogenicity of different batches varied considerably. The majority of icterogenic pools produced jaundice in only 1 or 2% of those transfused, but one small pool of 38 bottles gave rise to jaundice in 30% of the recipients. No cases of jaundice occurred among the 891 recipients of 2,273 bottles of blood who were surviving at the end of 5 months. There were also no cases among 876 non-transfused controls who had been in the same hospital wards at the same time as the transfused. Examination of hospital records of 1940-5 Service in-patients at an E.M.S. hospital reveals somewhat similar figures.¹³ There were 140 cases of jaundice among 1,396 injured or sick patients who were transfused and under observation 3 months or more after transfusion or injury or developed

jaundice within that period. There were 6 cases of jaundice among 6,250 injured patients who were not transfused.

The value of blood or blood products, properly used, in the treatment of certain surgical and medical conditions is unquestionable. During the war, at military hospitals and civilian hospitals dealing with air-raid casualties, there appears to have been a tendency to "give him a bottle of blood anyway," and in many cases it may have helped to turn the balance to recovery. In Dr. Vaughan's series 800 of the 2,040 transfused patients who were followed up died within 5 months of transfusion, and, of these, 769 died less than 2 months after transfusion. Thus 39% of the transfused cases were so ill that the possible value of the transfusion outweighed the possibility of ill effects such as jaundice. Though most reports of cases have involved only small groups and show a very low mortality rate from necrosis of the liver, there were 24 deaths in the group of 140 cases from an E.M.S. hospital.¹³ The higher mortality rate may be related to the combined effect of the hepatitis and the illness or injury for which the transfusion was given to military personnel.

The data available indicate that there are probably two different agents—that of infective (epidemic) hepatitis and that of homologous serum hepatitis—either of which may cause transfusion jaundice. As already mentioned, the causative agent of either disease may be circulating in the blood stream several days before the onset of symptoms and before there is detectable evidence of liver damage; but in those donating blood early in the onset of symptoms, when one might not be suspicious, there is probably evidence of liver dysfunction. Makari¹⁴ has suggested the routine use of the cephalin-cholesterol flocculation-test of Hanger for all donors' blood at the same time as the Wassermann reaction. Until a simple test for the presence of either agent is available the next best solution is a routine method of treatment of all pooled sera in order to inactivate any icterogenic agent present. None of the usual methods of heat or chemicals has proved effective so far, but experiments by Oliphant and his colleagues¹⁵ suggest that irradiation with ultra-violet light may prove satisfactory. Work done in England has shown that there

probably only a narrow margin between the dose which inactivate the icterogenic agent and leave the essential properties of the serum unchanged and that dose which will destroy the essential proteins. It is also possible that the albumin fraction may be able to withstand heating to the required inactivating temperature which would destroy the usefulness of whole serum or gamma globulin fraction. Following the satisfactory prevention of (epidemic) infective hepatitis by injections of immune gamma globulin, Grossman and his colleagues¹⁶ used this method in cases of transfusion jaundice with variable results. In one group of military patients given one dose on admission to hospital and one dose one month later the incidence of jaundice appeared to be less than in the uninoculated controls, but the gamma globulin apparently had no effect in another group given only one prophylactic injection and in a group of experimental human volunteers who were injected with a known icterogenic agent beforehand.

The danger of transfusion jaundice appears to lie chiefly in the use of pooled serums rather than in individual samples of whole blood. The present rate at which dried plasma is being consumed indicates that it is still being used indiscriminately and that its dangers are not appreciated. To reduce the risk of transmission of a hepatitis-producing agent, dried plasma is now being made from the smallest "workable" pools, but until improved methods of preparation can provide a guaranteed non-icterogenic product the golden rules for those giving transfusions should be: "Don't transfuse just for the sake of 'doing something.' Use whole blood where possible, but if pooled serum is necessary limit it to the least possible."

ON THE CREDIT SIDE

The authors of the medical history of the Second World War will find a rich quarry of information about the home front in the Ministry of Health's publication *On the State of the Public Health during Six Years of War*.¹ The volume resembles in form the Annual Reports which the Chief Medical Officers have made to the Ministry, and to the Local Government Board before it, and to the Privy Council and the General Board of Health before that, right back to 1856, but each of those reports was concerned with a single pedestrian year. They recorded small gains and losses, the declining incidence of one disease, the obstinate prevalence of another. On the whole they registered progress, especially since the beginning of this century, a period which has seen infant mortality decline by two-thirds and the tuberculosis death-rate halved. In the present publication, however, we have a record from the public health aspect of the fortunes and sufferings, the exertions and stresses, of the people of this country during the six hardest and grimmest years of their history. Even during the Civil War and other times of commotion and calamity the vast majority of the citizens must have slept peacefully in their beds. The national disturbance did not thrust itself into every dwelling and interrupt the ordinary commerce of social life. But during the first half of this fifth decade of the twentieth century families were disrupted as never before and human life reached an unheard-of level of devaluation. "Who dies if England live?" It may not be realized that the number of people killed in our country as a result of total war was equal to one-quarter, and the number injured to more than three-quarters, of those killed and wounded respectively in the British Armed Forces in all the theatres the world over. The civilian death-roll was 60,000, and the number of injured something like 218,000.

The strange paradox is that at a time when human life counted for so little, the men and women engaged in the conservation and improvement of public health achieved some of their greatest triumphs. Infant and child mortality is not a bad test of public health, and this reached new low levels. No disease showed a heavy epidemic prevalence with the exception of cerebrospinal fever, and even there, thanks to the use of sulphonamide derivatives, the lowest case-mortality was attained. In the ten years before the war the case-mortality of cerebrospinal fever was never below 50%; in 1930 the number of notifications was 674 and the

¹⁴ *J. Amer. med. Ass.*, 1945, 129, 991.

¹ H. M. Stationery Office. 5s.

number of deaths 635. But in 1940 and 1941, when the notifications soared into five figures, the death-rate was only 20%. Again, in spite of shortages of many kinds, the nutrition of the people was not worse at the end of the war than it had been at the beginning, and among children was somewhat better. Great advances were made in therapeutics, especially in chemotherapy, while "the discovery of the new insecticides," says Sir Wilson Jameson, meaning D.D.T. and gammexane, "may well have greater and more lasting effects on the health of the human race than any other discovery in the last six years." It was also during this destructive war, and as a consequence of it, that a new pattern of hospital service, co-operative and co-ordinated, was put into action, that a public health laboratory service was instituted which has become an integral part of the public health organization, that the civil nursing reserve was set up and enrolled 29,000 whole-time and as many part-time members, and that a blood transfusion service was established, enlisting a million donors.

The organization of hospital services and of medical personnel and supplies was on such a scale as to make it possible for this report to say that "less than 50,000 admissions [meaning admissions of air-raid casualties during the heavy night raiding period of 1940 and early 1941] spread over nine months obviously threw no great strain on the hospital accommodation, except for a few hours at a time in a small number of hospitals"; and again in the last months of the war, when a thousand long-range rocket bombs reached this country, killing 2,724 people and seriously injuring 6,691, we come once again upon the "obvious"—"obviously no strain was imposed upon the E.M.S. in dealing with hospitalized casualties which, spread over the 29 weeks of the attacks, averaged only 230 per week."

In this report the treatment is inevitably statistical, but figures can be impressive, such as the 163,500 beds waiting for casualties at the beginning of September, 1939, the 34 ambulance trains which during the war carried something like 220,000 patients, the thousand bus ambulances, of which the 220 in London alone took half-a-million stretcher and sitting cases. From D-day onwards the Emergency Medical Service received a stream of casualties from the Front in Western Europe, numbering before the year was out 80,500 by sea and 51,500 by air. The movement of casualties was only one of the forms of evacuation. The story of the transport of a million children from eighty evacuation areas to over a thousand reception areas has been often told, and the first wave of evacuation was followed by others, rising and falling with the tide of war. Then there was the despatch of 150,000 expectant mothers to emergency maternity homes, the evacuation from London of 7,600 chronic sick and 5,000 crippled and blind, and of 18,000 from the hospitals in the large towns of the provinces. Refugees to the number of 11,000 from Gibraltar, 30,000 from the Channel Islands, and others from Norway and Holland added to the problem. The transport was relatively a minor consideration, but all this movement entailed the provision of clinics, sick bays, maternity accommodation, nurseries, hostels, rest centres, canteens, and all of it meant certain health risks. Yet among the 150,000 women confined in emergency maternity homes the maternal death-

rate was only 0.8 per thousand, and even among the 30,000 admitted to the homes which had been upgraded for abnormal cases it was only 1.9.

The organization of the civil defence casualty services—the 2,000 first-aid posts ready at the outbreak of war, the 6,000 aid-points, the 800 mobile units, and so on—makes a thrilling chapter if the figures are read imaginatively and allowance is made for official under-statement. One of the strangest aspects of wartime England was presented by the shelters. To our descendants the accounts of the nightly scenes in underground London may well appear fantastic and incredible. Sometimes a million people were in the shelters. On one night there were 20,000 in Piccadilly Circus tube station. The conditions in some of the shelters at first were appalling, and at no time were they better than the worst pre-war living conditions in London. Yet no serious outbreak of epidemic disease occurred among these huddled multitudes. There was not even any serious increase in lousiness, thanks to health propaganda and the presence of the shelter warden. So far as can be ascertained from sample surveys, there was no increase in neurosis. The fact is that, hazardous as they were from the health point of view, the shelters housed a population which for various reasons was tough and resistant. The people were living on a planned diet of adequate rations of protective foods. If the shelters were full, the places of amusement were empty, and from the point of view of mass infection the picture theatre may be more perilous than a tube subway. Moreover, though the shelterers had to endure great discomfort, many of them enjoyed a new social experience. Morale was high, and unexpected patience, good temper, and even heroism were plentiful.

Amid all these tasks and emergencies many figures stand out, representative of their class or vocation, as exemplifying that "all-in-the-day's-work" courage which we like to think is a British characteristic. One of them is the civilian doctor, generally middle-aged or elderly, doing two or three men's work, with no young assistant at his elbow, with his partner away on service, with some portion of his neighbour's practice to look after, continually called upon to undertake new duties, to look after patients in E.M.S. and other hospitals, to act as part-time works doctor at the local factory, to serve as medical officer to the Home Guard, to staff the recruiting boards, to examine refugees and others, to attend—sometimes to have charge of—first-aid posts and train nursing and auxiliary staff, to visit the shelters, and, no matter how "dirty" the night or tiring the day, to turn out for "incidents": all this in addition to the ordinary round of the doctor. To show how great the burden must have been it is necessary only to quote one figure. By the end of 1942 more than half the total population of England and Wales resided in areas where there were more than 3,000 people to each general practitioner: the highest ratio was about one doctor to 4,300, and later on it rose in some cases to 4,500. The tribute paid by Sir Wilson Jameson to the civilian doctor is truly well deserved. No small share of the credit for maintaining the public health and morale during the six years of war should be accorded to those of our profession who, though they did not put on Service uniform, were inspired by the same sense of duty and self-forgetfulness as those who did.

BIOLOGICAL STANDARDIZATION

It would be useful if more people could know of the work of the Health Organization of the League of Nations in the field of biological standardization. Our civilization is believed to have been brought to the verge of destruction by the discoveries of scientists, and the non-scientific world asks its leaders to give their views in important broadcast talks on how this situation can be met. Their efforts to tell us are notably free from constructive suggestions. Yet the medical scientists have made a contribution to international co-operation which stands as a model for co-operation in wider and more important fields. The scientists themselves answer the question which perplexes the non-scientific world. Few, however, know of this work; even medical men themselves show little interest or pride in it; yet it is scarcely possible to exaggerate its significance.

The latest Bulletin of the Health Organization¹ gives a summary of the steps which have been taken to ensure the use of international standards for serums, hormones, and vitamins, and of the continuous research which has been organized in different countries in relation to these standards. Described in such terms the purpose of the work and the magnitude of the project alike seem small, but this description gives no conception of the number of problems which have been the subject of co-ordinated study and of the influence this work has had in bringing workers of many nationalities into close co-operation. There is no longer any purpose in concealing the fact that the main impulse to the progress of this work has been supplied by those in the National Institute for Medical Research at Hampstead. Other countries, however eminent in medical science, have not yet taken the constructive interest in this work which its importance demands. Our greater sense that the welfare of those outside our own land affects our own welfare is shown here as well as in other fields. It is surprising to state that the work has gone on during the war without any formal interruption, though the volume of co-ordinated research in different countries has been very small. In the very middle of the war—in 1942—a provisional international standard for heparin was set up. The need for international agreement on penicillin was compelling enough for an international conference to be held in London in October, 1944, so that the earliest opportunity afforded by the decline of the war was taken for a major advance.

Among other problems of a more unusual kind which have been studied are the standardization of anti-snake-venom sera, of poliomyelitis convalescent serum, and of typhoid serum. Much attention has been given to the hormones of the pituitary anterior lobe, and the knowledge accumulated will undoubtedly be useful when these hormones have been sufficiently separated from one another to make possible their clinical use. The work on the gonadotrophic hormone obtained from the urine of pregnant women was carried out in no fewer than 32 laboratories, which were South African, American, Brazilian, British, Canadian, Danish, French, German, Hungarian, and Dutch. This was directed to the selection of an international standard and the definition of a unit as the activity present in an agreed weight of this standard. It forms a very good example of the width of the scope of international endeavour in this field.

The organization dealing with biological standards has been so great a success that every effort should be made to continue it and perhaps to enable its terms of reference to be extended so as to increase its great usefulness further.

¹ Bulletin of the Health Organization of the League of Nations. Vol. XII, No. 1, 1945-6. London: Allen and Unwin. (5s. net.)

This highly important part of the Health Organization's work will be continued under the World Health Organization, and in the meanwhile under the Interim Health Commission.

HERPES ZOSTER AND VARICELLA

The relationship between herpes zoster and varicella is very much more puzzling than the mere fact of their common clinical association would lead one to believe. That children in contact with cases of herpes zoster may develop varicella is now generally recognized, although the reverse transmission is rare; nevertheless cross-immunity, studied either clinically or by serological methods, does not appear to be complete.

There is perhaps something still to be learned from the purely clinical study of the respective features and the association of the two conditions, and this aspect of the subject is reviewed by S. Dahl,¹ of Viborg. Varicella has been a notifiable disease in Denmark since 1938, and it is therefore possible to state its seasonal incidence exactly: this has a maximum in mid-winter. The maximum incidence of herpes zoster on the other hand is in the warmer months of the year. According to the findings of seventeen authorities quoted it is variable, but the majority observe a high incidence in April and May; and in Dahl's own figures, derived from hospitals in Copenhagen, there was a steady rise to a peak in August. The difference in age incidence is of course well known, that of varicella falling steadily from a maximum in infancy, whereas that of herpes zoster rises to a peak in the third decade with a secondary smaller rise in the fifth. There is also a sex difference: varicella attacks both sexes equally, while herpes zoster much more frequent in males than in females. A fourth point of distinction is the association of herpes zoster with other infective conditions: among several of these noted in the Copenhagen series syphilis was the most frequent. All these facts require to be explained in any hypothesis accounting for the association of the two conditions. I Dahl's view they are inconsistent with the idea of common aetiology.

VASCULAR CHANGES IN RHEUMATOID ARTHRITIS

Not long after the important work by Lewis² on the capillary circulation in health and disease, Pemberton³ called attention to deficient circulation in the capillaries in rheumatoid arthritis, and Simpson⁴ demonstrated by oscillography a spastic condition of the blood vessels of the fingers in cases of arthritis. Later, Bisset and Woodmansey⁵ by means of photomicrographs showed a deficiency in the number of capillary loops and attenuation in their calibre, and they also found that the effect of histamine in producing dilatation of the superficial vessels was less marked in rheumatic subjects. Kovacs and others⁶ noted a great reduction in the number of capillaries in the peripheral tissues in patients with rheumatoid arthritis, and a greatly increased blood supply in the articular tissues. On the other hand, Hench⁷ was unable to find any consistent alteration in the size of the capillaries or the capillary flow in a large number of cases of rheumatoid arthritis and degenerative diseases.

Naide, Sayen, and Comroe, whose early death is a serious loss to rheumatology, have determined the basal

vascular tone in a large number of normal controls, and died fifteen patients with rheumatoid arthritis, whose ages varied from 14 to 65 years. They took the temperature of fingers and toes under cool conditions, and again during the application of moderate heat to the trunk. Digits affected by arthritis remained warm, while in cool conditions, longer than those not so affected. This difference, however, may be due simply to the inflammatory process in the joints. They also found a high basal vascular tone in patients with rheumatoid arthritis, though not abnormally high; some 30 to 40% of normal individuals showed the same tone. These authors claim that the dissociated response in affected digits enables a diagnosis of rheumatoid arthritis to be reached earlier than by other methods, but the proofs they advance are not convincing.

It is also suggested that this response may be a guide to treatment, which they propose might take the form of repeated lumbar paravertebral block, or periods of continuous caudal anaesthesia. Both methods seem somewhat drastic. Local heat would appear to be simpler and equally efficacious. More observations on a larger number of patients with a more rigid selection of controls will be required before their conclusions can be accepted, or their value proved.

CAROTID SINUS SYNCOPE

The role of a hypersensitive carotid sinus in the production of syncope and other vague cerebral symptoms is well known and has been ably recorded by S. O. Weiss and others.^{1,2} Indeed, the attempt to reproduce an attack at the bedside by manual or other forms of stimulation in the region of the bifurcation of the common carotid artery is a clinical commonplace. Besides pallor and faintness, lypsaesthesiae and twitching may be experienced in the contralateral limbs. Consciousness may be lost and the convulsive movements may become generalized. That this diagnostic measure may not be entirely innocuous was shown in 1941 by a patient described by J. Marmor and M. R. Sapirstein,³ who developed a thrombosis in the anterior cerebral arteries after stimulation of the carotid sinus. In 1945 S. A. Levine⁴ recorded another case of hemiplegia following this procedure. The most impressive body of evidence has been marshalled by J. M. Askey⁵ in a recent paper giving notes of ten cases in which carotid stimulation was followed by hemiplegia, either transient or permanent. Of these, seven were unquestionably cases of immediate and direct ill effect; in two others the hemiplegia was a "possible" result; and in one case a unilateral paralysis did not develop until twenty-four hours after the carotid stimulation.

How does this catastrophe arise? In all cases the hemiplegia developed on the side opposite the carotid stimulated. In at least one case the mechanical pressure in question was quite light. Unilateral cerebral ischaemia from reflex vasoconstriction is therefore more probably the cause than a general systemic fall of blood pressure due to vasodepression (perhaps with bradycardia), or cardiac inhibition. G. L. Engel and his collaborators⁶ support this opinion with their electroencephalographic studies of carotid sinus syncope. Many of Askey's patients had diseased arteries. Perhaps the lesson to be learned from these disasters is that mechanical stimulation of the carotid sinus should be applied with caution in arteriosclerotic or elderly subjects.

TUBERCULOSIS AND JUVENILE MALNUTRITION IN AUSTRIA

Concern expressed in British medical circles at the steadily rising figures for tuberculosis in Europe is echoed in Austria in view of the prolonged food crisis and lack of adequate facilities for treating the disease. Medical experts are of opinion that the younger generation of the country is in considerable danger. It is stated that there are at present 28,000 registered cases of tuberculosis for which treatment is needed but that there are probably many more not yet registered. The death rate from tuberculosis in Austria shows an increase of 13 per 10,000 of population during the last 16 years. The causes are malnutrition, overwork, and often the direct pressure of the Nazi regime. Many ex-soldiers also contracted the disease. It is feared that the incidence will continue to rise because sanatorium facilities and medical supplies are insufficient and many of the cases are contagious. The threat is greatest to children, and it is estimated that 300,000 children are potential patients. The most urgent need, states the Vienna Advisory Council, is for adequate treatment to be made available immediately in order to reduce the danger of infection, and also to ensure a better-balanced diet.

Juvenile health in Vienna is deteriorating at a rate that is causing anxiety to the Austrian Government. In an inquiry into the health and living conditions of school-children, young apprentices, and auxiliary workers between the ages of 14 and 18, the Vienna Labour Chamber found only 28% of the girls and 11% of the boys to be really healthy and of normal weight; 34% of the girls and 64% of the boys were more than 20 lb. underweight, showing a sharp progressive decline each month since February. Housing and living conditions were found to be extremely bad, with thousands of apprentices and juvenile workers living with from two to eight other people in kitchens and small rooms.

A COLLECTION OF TUMOURS

The report of the curator of the laboratory of the Royal College of Physicians of Edinburgh (Dr. R. Cranston Low) states that the collection of tumours in the research department of the laboratory has now passed the 20,000 mark and may be described as a highly special research collection. Every tumour specimen has been filed and indexed, reported and commented on, preserved in block form, and made immediately accessible under the two main headings of type of locality, as well as lesser headings. The collection is largely intended to supply the research worker with material for reference concerning normal and abnormal structure and embryological material, with special insistence on its human, not animal, character. Much of the material in this collection comes under the head of the science of "gerontology," especially structural changes with age, the changes in organs and tissues which occur at all age periods from the cradle, or before it, to the grave. The collection has been instituted and maintained during the past seventeen years by Lieut.-Col. W. F. Harvey, who has recently resigned the superintendence of the laboratory, though he is continuing his work as histologist. The new superintendent is Dr. Cranston Low.

Sir Maurice Cassidy will deliver the Harveian Oration before the Royal College of Physicians of London on St. Luke's Day, Friday, Oct. 18, at 3 p.m., at the College, Pall Mall East. Subject: Coronary Disease.

THE WORLD HEALTH ORGANIZATION

BY

MELVILLE D. MACKENZIE, M.D., D.P.H., D.T.M.&H.

*A Principal Medical Officer, Ministry of Health; United Kingdom
delegate to the World Health Conference, New York, 1946*

An international health conference for the establishment of an international health organization was convened by the Economic and Social Council of the United Nations in the City of New York from June 19 to July 22, 1946.* The Conference used as the basis of discussion proposals adopted by a technical preparatory committee of experts set up by the Economic and Social Council of the United Nations. This committee met in Paris in March, 1946.

As a result of the deliberations of the Conference the following instruments were drawn up:

(a) Constitution of the World Health Organization.

(b) Arrangement for the establishment of an Interim Commission of the World Health Organization.

(c) Protocol concerning the Office Internationale d'Hygiène Publique.

The texts of each of these documents in Chinese, English, French, Russian, and Spanish, all of which were equally authentic, were signed by the following 61 nations:

Albania	Ethiopia	Philippine Common-
Argentina	Finland	wealth
Austria	France	Poland
Australia	Greece	Portugal
Belgium	Guatemala	Saudi Arabia
Bolivia	Haiti	Siam
Brazil	Honduras	Switzerland
Bulgaria	India	Syria
Byelorussian Soviet	Iran	Transjordan
Socialist Republic	Iraq	Turkey
Canada	Italy	Ukrainian Soviet
Chile	Lebanon	Socialist Republic
China	Liberia	Union of Soviet
Columbia	Luxembourg	Socialist Republics
Costa Rica	Mexico	Union of South
Cuba	Netherlands	Africa
Czechoslovakia	New Zealand	United Kingdom
Denmark	Nicaragua	United States of
Dominican Republic	Norway	America
Ecuador	Panama	Uruguay
Egypt	Paraguay	Venezuela
Eire	Peru	Yugoslavia
El Salvador		

The United Kingdom signed all three instruments without reservation as to ratification.

In view of the extensive functions agreed to in the Constitution of the World Health Organization, which cover most branches of medicine, a somewhat detailed summary of the work and machinery of the new organization cannot fail to be of interest to very many of the medical profession who are anxious to know the lines along which they, or technical organizations in which they are interested, may be able to contribute to ensure the success of this new body.

* The Governments of the following States were represented at the Conference by delegates: Argentina, Australia, Belgium, Bolivia, Brazil, Byelorussian Soviet Socialist Republic, Canada, Chile, China, Columbia, Costa Rica, Cuba, Czechoslovakia, Denmark, Dominican Republic, Ecuador, Egypt, El Salvador, Ethiopia, France, Greece, Guatemala, Haiti, Honduras, India, Iran, Iraq, Lebanon, Liberia, Luxembourg, Mexico, Netherlands, New Zealand, Nicaragua, Norway, Panama, Paraguay, Peru, Philippine Commonwealth, Poland, Saudi Arabia, Syria, Turkey, Ukrainian Soviet Socialist Republic, Union of Soviet Socialist Republics, Union of South Africa, United Kingdom, United States of America, Uruguay, Venezuela, Yugoslavia.

In addition, the Governments of the following States were represented by observers: Albania, Austria, Bulgaria, Eire, Finland, Hungary, Iceland, Italy, Portugal, Siam, Sweden, Switzerland, Transjordan.

The Allied Control Authorities in Germany, Japan, and Korea were represented by observers. The following international organizations were also represented by observers: Food and Agriculture Organization of the United Nations, International Labour Organization, League of Red Cross Societies, Office Internationale d'Hygiène Publique, Pan-American Sanitary Bureau, Provisional International Civil Aviation Organization, The Rockefeller Foundation, United Nations Educational Scientific and Cultural Organization, United Nations Relief and Rehabilitation Administration, and World Federation of Trade Unions.

Principles and Functions

The work of the World Health Organization is based on the following principles:

Health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.

The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, or economic or social condition.

The health of all peoples is fundamental to the attainment of peace and security and is dependent upon the fullest co-operation of individuals and States.

The achievement of any State in the promotion and protection of health is of value to all.

Unequal development in different countries in the promotion of health and control of disease, especially communicable disease, is a common danger.

Healthy development of the child is of basic importance; the ability to live harmoniously in a changing total environment is essential to such development.

The extension to all peoples of the benefits of medical, psychological, and related knowledge is essential to the fullest attainment of health.

Informed opinion and active co-operation on the part of the public are of the utmost importance in the improvement of the health of the people.

Governments have a responsibility for the health of their peoples which can be fulfilled only by the provision of adequate health and social measures.

In conformity with these principles, the functions of the World Health Organization will be:

(a) To act as the directing and co-ordinating authority on international health work.

(b) To establish and maintain effective collaboration with the United Nations, specialized agencies, governmental health administrations, professional groups, and such other organizations as may be deemed appropriate.

(c) To assist Governments, upon request, in strengthening health services.

(d) To furnish appropriate technical assistance and, in emergencies, necessary aid upon the request or acceptance of Governments.

(e) To provide or assist in providing, upon the request of the United Nations, health services and facilities to special groups, such as the peoples of trust territories.

(f) To establish and maintain such administrative and technical services as may be required, including epidemiological and statistical services.

(g) To stimulate and advance work to eradicate epidemic, endemic, and other diseases.

(h) To promote, in co-operation with other specialized agencies where necessary, the prevention of accidental injuries.

(i) To promote, in co-operation with other specialized agencies where necessary, the improvement of nutrition, housing, sanitation, recreation, economic and working conditions, and other aspects of environmental hygiene.

(j) To promote co-operation among scientific and professional groups which contribute to the advancement of health.

(k) To propose conventions, agreements, and regulations, and to make recommendations with respect to international health matters, and to perform such duties as may be assigned thereby to the Organization and are consistent with its objective.

(l) To promote maternal and child health and welfare and to foster the ability to live harmoniously in a changing total environment.

(m) To foster activities in the field of mental health, especially those affecting the harmony of human relations.

(n) To promote and conduct research in the field of health.

(o) To promote improved standards of teaching and training of health workers and the medical and related professions.

(p) To study and report on, in co-operation with other specialized agencies where necessary, administrative and social techniques affecting public health and medical care from preventive and curative points of view, including hospital services and social security.

(q) To provide information, counsel, and assistance in the field of health.

(r) To assist in developing an informed public opinion among all peoples on matters of health.

(s) To establish and revise as necessary international nomenclatures of diseases, of causes of death, and of public health practices.

- (i) To standardize diagnostic procedures as necessary.
- (ii) To develop, establish, and promote international standards with respect to food, biological, pharmaceutical, and similar products.
- (v) Generally to take all necessary action to attain the objective of the Organization.

Membership and Associate Membership

Membership in the World Health Organization is open to States, subject to certain conditions set out in the Constitution. In addition, provision is made for associate membership under certain conditions in the case of territories not responsible for the conduct of their international relations.

Organs

The work of the World Health Organization will be carried out by:

- (a) The World Health Assembly.
- (b) The Executive Board.
- (c) The Secretariat.

The World Health Assembly

The World Health Assembly will be composed of delegates representing Member States, each Member being represented by not more than three delegates, one of whom should be designated as chief delegate. These delegates should be chosen from among persons most qualified by their technical competence in the field of health, preferably representing the national health administration of the Member. The Health Assembly will meet in regular annual session and any such special sessions may be necessary. Among the functions of the Health Assembly will be those of:

- (1) determining policies of the Organization;
- (2) naming the Member States entitled to designate a person to serve on the Executive Board;
- (3) reviewing and approving reports and activities of the Executive Board and the Director-General, and instructing the Board in regard to matters upon which action, study, investigation, or report may be considered desirable;
- (4) supervising the financial policies of the Organization, and reviewing and approving the budget;
- (5) inviting any organization, international or national, governmental or non-governmental, which has responsibilities related to those of the Organization, to appoint representatives to participate in its meetings or in those of the committees and conferences convened under its authority;
- (6) considering the recommendations bearing on health made by the General Assembly, the Economic and Social Council, the Security Council, and Trusteeship Council of the United Nations;
- (7) promoting and conducting research in the field of health by the personnel of the Organization, by the establishment of its own institutions or by co-operating with official or non-official institutions of any Member; and
- (8) taking any other appropriate action to further the objective of the Organization.

The Health Assembly will also have authority to adopt conventions or agreements with respect to any matter within the competence of the Organization.

Furthermore, the Health Assembly will have authority to adopt regulations concerning:

- (a) sanitary and quarantine requirements and other procedures to prevent the international spread of disease;
- (b) nomenclatures with respect to diseases, causes of death, and public health practices;
- (c) standards with respect to diagnostic procedures for international use;
- (d) standards with respect to the safety, purity, and potency of biological, pharmaceutical, and similar products moving in international commerce; and
- (e) advertising and labelling of biological, pharmaceutical, and similar products moving in international commerce.

Such regulations will come into force for all Member States after due notice has been given of their adoption by the Health Assembly, except for such Members as may notify the Director-General of rejection or reservations within the period stated in the notice.

The Executive Board

The Executive Board will consist of 18 persons designated by as many Member States. The Health Assembly, taking into account an equitable geographical distribution, will nominate the Member States entitled to designate a person to serve on the Board. Each of these Member States should appoint to the Board a person technically qualified in the field of health. Among the functions of the Board will be those of:

- (a) giving effect to the decisions and policies of the Health Assembly and acting as its executive organ;
- (b) submitting to the Health Assembly a general programme of work covering a specific period;
- (c) studying all questions within its competence; and
- (d) taking emergency measures to deal with events requiring immediate action.

The Secretariat

The Secretariat will comprise the Director-General and such technical and administrative staff as the Organization may require. The Director-General will appoint the staff of the Secretariat. The paramount consideration in the employment of the staff shall be to ensure that the efficiency, integrity, and internationally representative character of the Secretariat shall be maintained at the highest level. Due regard should be paid to the importance of recruiting the staff on as wide a geographical basis as possible.

In the performance of their duties the Director-General and the staff shall not seek or receive instructions from any Government or from any authority external to the Organization. They shall refrain from any action which might reflect on their position as international officers. Each Member State of the Organization on its part undertakes to respect the exclusively international character of the Director-General and the staff and not seek to influence them.

Arrangements

Conferences.—The Health Assembly or the Executive Board may convene local, general, technical, or other special conferences to consider any matter within the competence of the Organization, and may provide for the representation at such conferences of international organizations and of national organizations, governmental or non-governmental.

Headquarters.—The location of the Headquarters of the Organization will be determined by the Health Assembly after consultation with the United Nations.

Regional Arrangements.—The Health Assembly will from time to time define the geographical areas in which it is desirable to establish a regional organization. Each regional organization will consist of a regional committee and a regional office. Regional committees will be composed of representatives of the Member States and associate Members in the regions concerned. Among the functions of the regional committees will be those of:

- (a) formulating policies governing matters of an exclusively regional character;
- (b) supervising the activities of the regional office;
- (c) suggesting to the regional office the calling of technical conferences and such other additional work or investigation in health matters as would promote the objective of the Organization within the regions;
- (d) recommending additional regional appropriations by the Governments of the respective regions, if the proportion of the central budget of the Organization allotted to that region is insufficient for the carrying out of the regional functions; and
- (e) carrying out such functions as may be delegated to the regional committee by the Health Assembly, the Board, or the Director-General.

It is further provided that the Pan-American Sanitary Organization and all other inter-governmental regional health organizations in existence prior to the date of signature of the Constitution shall in due course be integrated with the World Health Organization.

Reports submitted by Member States.—Each Member State will report annually to the Organization on the action taken and progress achieved in improving the health of its people, and also upon the action taken with respect to recommendations made to it by the Organization and with respect to

conventions, agreements, and regulations. In addition, each Member State will communicate promptly to the Organization important laws, regulations, official reports, and statistics pertaining to health which have been published in the State concerned. Finally, each Member State will transmit statistical and epidemiological reports to the Organization, and, upon the request of the Executive Board, such additional information pertaining to health as may be practicable.

Relations with other Organizations.—The World Health Organization will be brought into relation with the United Nations as one of its specialized agencies. The Organization will also establish effective relations and co-operate closely with such other inter-governmental organizations as may be desirable, and may, on matters within its competence, make suitable arrangements for consultation and co-operation with non-governmental international organizations and with national organizations, governmental or non-governmental.

The constitution of the World Health Organization will come into force when 26 Members of the United Nations have become parties to it by signature without reservation or by signature followed by ratification.

Interim Health Commission

In view of the very large number of Governments (61) who signed the Constitution in New York on July 22, 1946, it is expected that the necessary number of ratifications will be received in a relatively short time, and that the World Health Organization will hold its first Assembly in the spring or early summer of 1947. In the meantime the World Health Conference has set up an Interim Health Commission to do the preparatory work for the first meeting of the World Health Assembly and to carry out certain specific pieces of work.

The Interim Health Commission consists of 18 persons, technically qualified in the field of health, designated by the following States:

Australia	Liberia	United Kingdom
Brazil	Mexico	United States of America
Canada	Netherlands	
China	Norway	Union of Soviet Socialist Republics
Egypt	Peru	
France	Ukrainian Soviet Socialist Republic	Venezuela
India		Yugoslavia

The functions of the Interim Health Commission are:

(a) To convoke the first session of the World Health Assembly as soon as practicable and to prepare the agenda for the first meeting.

(b) To enter into negotiations with the United Nations with a view to the preparation of an agreement to provide for effective co-operation between the two organizations in the pursuit of their common purpose.

(c) To take all necessary steps to effect the transfer from the United Nations to the Interim Commission of the functions, activities, and assets of the League of Nations Health Organization.

(d) To take all necessary steps for the transfer to the Interim Commission of the duties and functions of the Office Internationale d'Hygiène Publique.

(e) To take all necessary steps for assumption by the Interim Commission of the duties and functions entrusted to U.N.R.R.A. by the International Sanitary Conventions of 1944.

(f) To enter into the necessary arrangements with the Pan-American Sanitary Organization and other existing inter-governmental regional organizations with a view to their integration within the World Health Organization.

(g) To study the question of relations between the World Health Organization and non-governmental international organizations and national organizations.

(h) To undertake initial preparations for revising, unifying, and strengthening existing international sanitary conventions.

(i) To review existing machinery, and to undertake such preparatory work as may be necessary in connexion with the next decennial revision of the *International List of Causes of Death* and the establishment of international lists of causes of morbidity.

(j) To consider any urgent health problem which may be brought to its notice by any Government, to give technical advice in regard thereto, to bring urgent health needs to the attention of Governments and organizations which may be in a position to assist, and to take such steps as may be desirable to co-ordinate any assistance such Governments and organizations may undertake to provide.

The Secretariat of the Interim Health Commission consists of a medical executive secretary and technical and administrative staff. The Interim Commission will cease to exist when the first meeting of the Health Assembly takes place.

The Commission has already held six meetings and appointed three committees: (a) Administration and Finance; (b) Epidemiological Intelligence and Quarantine; and (c) Relations with Existing Organizations. The next meeting of the Interim Commission will be held in Geneva in November, 1946.

To complete the picture, reference should be made to the protocol signed by 61 Governments by which "the Governments signatory to the protocol agree that, as between themselves, the duties and functions of the Office Internationale d'Hygiène publique shall be performed by the World Health Organization or its Interim Commission and that, subject to existing international obligations, they will take the necessary steps to accomplish this purpose."

Comments

A study of the summary set out above of the Constitution of the World Health Organization and other relevant documentation will show that the new Organization differs fundamentally in both its structure and the extent of its functions from those of the League of Nations Health Organization, and promises to have a definitely larger membership and a much greater budget. Thus, for instance, it will be recollected that the Health Committee of the latter consisted only of experts appointed in purely personal capacity who were not representative of their Governments. Consequently, the Health Committee of the League of Nations was a purely advisory body, and the fact that Governments were in no way bound by any of its decisions or recommendations resulted too frequently in little or no action being taken on any recommendations made. On the other hand, the delegates to the World Assembly will represent their Governments, and, moreover, Governments, by signing and accepting the Constitution, accept definite responsibilities and obligations. Again, the World Health Organization has authority to adopt conventions and agreements with respect to any matter within the competence of the Organization, as well as regulations in respect of certain specified matters. These regulations, once adopted by the World Health Assembly, become binding automatically on State Members, except such as may notify their objection or reservation within a period to be stated in the notice.

In conclusion, a most striking feature of the Conference was the wholehearted manner in which all the delegates participated in the work. Without exception they adopted throughout a constructive attitude and played a full part in all the activities of the Conference.

The Conference can be regarded as a real success, and the Constitution signed by the 61 nations was eminently satisfactory from the United Kingdom point of view. The British Government will spare no pains to make the work of the World Health Organization successful, and it is certain that all British organizations in the field of health, as well as individual medical men, whatever their expert knowledge happens to be, will desire to co-operate towards the same end.

EDUCATIONAL TREATMENT FOR HANDICAPPED CHILDREN

The problems of providing special educational treatment for children suffering from disability of mind or body are dealt with in a pamphlet published by the Ministry of Education. Local education authorities now have new responsibilities for the provision of suitable education for these children, and the pamphlet is intended mainly for their guidance and to help teachers in the discharge of this difficult and important duty.

At any time after a child is two years old the parent may ask to have him examined to see if he requires special educational treatment. The authority is bound to have this done and if it is found that the child requires such treatment this must be provided if the parent wishes. Children at school suspected

of a disability will be medically examined, by specialists if necessary, and the local education authority will consider in the light of medical and other advice what kind of special educational treatment they should be given. In serious cases this will be provided in a special day or boarding school and in other cases arrangements will be possible in the ordinary school. For instance, partially deaf children should have hearing aids and courses of lip reading at school when recommended by the school medical officer. These children would be carefully watched and if they failed to make progress they should be sent to special schools. For delicate children there is a need for more boarding schools, but some provision can be made for them in the newer hygienic primary and secondary schools, where meals and milk are available. When rest after dinner is recommended, stretcher beds and blankets should be provided.

Subnormal and Maladjusted Children

The educationally subnormal children, including those formerly known as "educable mental defectives" and the dull or backward child, form the largest category requiring special educational treatment. The number may be as high as 10%. In the larger urban areas, day and boarding schools will be needed, and arrangements will also be necessary in the ordinary schools. In almost all schools of moderate size facilities will be required for at least a small group of children. These should not be segregated from other children or from the corporate life of the school. They will need special help in certain parts of their work. This problem must be faced by the modern school, and the staff should experiment with enterprising methods and organization for dealing with it.

In all types of area there will be a small number of educationally subnormal children who require for their own good to be taken away from their homes and educated in a boarding special school. These will include unstable children, children from unsuitable homes, those who are truants or unmanageable in a day special school, and those committed to the care of the authority by the Courts. In no case should a child who is recognized as ineducable be allowed to attend school. In the past this has sometimes been allowed on sentimental grounds. One detrimental or low-grade child can create havoc in a class, distract the children, occupy the full attention of the teacher, and bring the school into disrepute among parents and the public. It is too great a price to pay for kind-hearted acquiescence in his continued attendance. For the maladjusted child the Ministry suggests the establishment of child guidance clinics, the appointment of more education psychologists, boarding-out arrangements for certain children with carefully chosen foster-parents, boarding homes for children who may attend ordinary schools, and special boarding schools.

The pamphlet also includes suggestions for the education of physically handicapped children, for blind and partially sighted children, and for children with speech defects.

LECTURES ON CHILD DEVELOPMENT

The staff of the Provisional National Council for Mental Health, in their contacts with school medical officers, have frequently heard expressed the opinion that the enlargement of the duties of the medical officer working in a local authority makes it increasingly important for him to know something of the normal mental and emotional development of children. The provisions of the new Education Act concerning difficult young children are a case in point and the Council hopes at a later date to incorporate a section on the subject in the courses it runs for medical officers. Meanwhile it is thought that there might be a group of medical officers in and near London who would be interested in a short series of lectures on the emotional development of the normal child from infancy to adolescence and who would find information on normal child development of service to them in their work in other fields beyond that of certification. The Council has therefore planned a course of ten weekly lectures to meet the needs of such officers. It will be simple in its content, and the bearing of the material on the practical problems of medical and administrative work will be made evident. The lectures will be given at 39, Queen Anne Street, W.1, at 6 p.m. on Wednesdays beginning Oct. 9, and the fee is £2 2s. Applications should be sent to the Education Secretary, P.N.C.M.H., at that address by Oct. 6.

STREPTOMYCIN

The Government, as represented by the Ministry of Health, the Medical Research Council, and the Ministry of Supply, are co-operating with various firms in connexion with the pilot scale production of streptomycin. The firms at present concerned are Boots Pure Drug Co., Distillers Co., and Glaxo Laboratories, who are all established penicillin producers, and the Heyden Chemical Co., who propose to install a factory to produce streptomycin (and penicillin) at Ardrossan in Scotland.

For many months streptomycin will be available only for clinical trial under the auspices of the Medical Research Council, and it is hoped that these trials will begin before the end of this year. Trials must necessarily be prolonged since the conditions for which it is hoped streptomycin treatment will prove advantageous require treatment over a period of some months. In any event release to the general medical profession could not occur until substantial production is in operation, by which time the trials should have provided the information on which advice to the medical profession as to the mode of use of streptomycin can be based.

A SELECTION BUREAU FOR INDIA

An office known as the Employment Selection Bureau has been established by the Government of India at New Delhi with the purpose of stimulating, planning, and giving technical direction to various projects of psychological-psychiatric significance in which the Government is interested.

Since December, 1945, the Bureau* has been concerned chiefly with the assessment and preliminary selection of Indian candidates for administrative appointments in the Central and Provincial Government services, and has set up for this work three civil selection boards similar in character to those employed since 1942 in a number of the Allied Armed Forces. Candidates appear before these boards for a period of three days, during which the technical staff composed of a psychiatrist, a psychological officer with assistants, and group testing officers undertake by means of tests, interviews, and observation in a variety of social situations an appraisal of each candidate's qualities relative to his prospective Government employment.

While at the moment the Bureau's principal commitment is to the civil selection boards' programme, it is expected that in the future, with increase in trained staff, an extension of its work can be made into other personnel activities in the Government services, the selection and guidance of secondary school pupils, industrial relations problems, and perhaps additional but at present less definitely indicated fields of child delinquency, mental hygiene, the study of cultural conditions as a basis for social and economic development, and the like. It is generally construed as a function of the Bureau to assist in the stimulation and development of sound practice in these fields in such a way as to make this growth an integral part of India's own post-war pattern of progress. As a consequence, close relations with the Indian universities and other institutions in the procurement and training of staff and in the actual field work undertaken are considered to be of the highest importance.

The Director of the Employment Selection Bureau is Brigadier H. Vinden, until recently Director of Selection of Personnel, Indian Army, and its secretary is Mr. C. K. Phillips. Dr. D. J. Watterston, who was formerly consultant psychiatrist for 21 Army Group, is the Bureau's adviser in psychiatry, and Dr. N. W. Morton, on temporary leave of absence from McGill University and from 1941 a member of the personnel selection staff of the Canadian Army, is its adviser in psychology.

A report on the work of the St. Thomas's Hospital Samaritan Fund and Lady Almoner's Department has recently been issued. The nucleus of the fund was established in 1852 by the Hospital Governors investing £2,000 "to comfort the forlorn, to assist the struggling, to raise up the fallen." Needs to say, though, that social legislation has altered the form of charity, money is now urgently needed to maintain the Fund. The Almoner's Department, which administers the Fund, was founded in 1915, Miss Cummins being appointed Principal. It was largely due to her energy and imagination that welfare of the sick attained its present importance. A well-deserved tribute is paid to the courage, tact, and efficiency displayed by members of the Department during the hardships on London.

PUBLIC HEALTH IN THE WAR YEARS

MINISTRY OF HEALTH RETROSPECT

The twenty-first report of the Chief Medical Officer of the Ministry of Health¹ takes the form—not of an annual statement covering a single year of peace, but of a narrative of the state of the public health and the medical work of the Ministry “during the trials, the mercies, the efforts, and the final triumphs of six years of the grimmest struggle Britain has endured since the Conquest.” The facts and figures, as Sir Wilson Jameson says, need no interpreter—they speak for themselves. He pays many tributes—to the Medical Research Council, the Medical Directors of the Services, the Ministries of Education, Labour and National Service, Food, and Supply, the London County Council, the Central Medical War Committee, the general practitioners who remained in civil life, public health medical officers, his colleagues in his own department, and his predecessor, Sir Arthur MacNalty, whose wise policy during the period of pre-war preparation and the first fourteen months of the war, during which he held office, greatly facilitated his own task.

During the war years the birth-rate for England and Wales rose steadily, reaching 17.7 in 1944 (the last complete year to which this report relates), its highest point since 1926. The death-rate has remained steady, and in 1944 was 12.7. The principal certified causes of death were in the same order each year—diseases of the heart a long way first, followed by cancer, intracranial lesions of vascular origin, bronchitis, tuberculosis, and diseases of the digestive system. Infant mortality, though it went as high as 60 per 1,000 births in 1941, came down to 45 in 1944. There were marked reductions in the large towns—in Liverpool, for example, infant mortality fell from 74 in 1938 to 58 in 1944. Not only in infancy but at every year of age from one to fourteen the mean annual death-rates for 1940–44 were below the rates for any pre-war year, and this in spite of the deaths of some 7,000 children due to enemy action and an increase in accidental deaths brought about by war conditions.

Absence of Serious Epidemics

The war period was marked by the absence of serious epidemics, except for the unprecedented epidemicity of cerebro-spinal fever, the notifications of which in 1940 and 1941 were some ten times those of 1938; but the disease was attended by the lowest fatality rate on record, thanks to the use of sulphonamide derivatives in treatment. Two short epidemics of mild influenza occurred during the six war winters. Typhoid fever was less prevalent during every war year (except 1941) than in the pre-war year 1938, but in the earlier part of the war there were three considerable outbreaks of paratyphoid fever of a mild type. Notifications of dysentery showed a large increase in 1944. The commonest type of dysentery by far is that due to the *Sonne bacillus*. The increased prevalence the more disquieting because it had been hoped that the revisions of the Food and Drugs Act, 1938, would have notably lessened the incidence of intestinal infections. The number of outbreaks of food poisoning during the war years was 1,319, with 2,544 cases and 35 deaths. It is mentioned that the importation of dried egg from America appears to have been responsible for the introduction of an entirely new series of *Salmonella* types. In 1943 seven outbreaks, involving 95 persons, were traced to this source, and it is considered likely that earlier outbreaks in which alien types of *Salmonella* were found had the same origin.

The incidence of scarlet fever seems to have been unaffected by war conditions, but case mortality reached an unprecedented low level. Measles was severely epidemic in 1940 and 1941, but the deaths even in the epidemic years were only 75% of the average number for the quinquennium 1935–9. Low records for diphtheria have been established, though the comment is made that far more children were killed by this preventable disease during the war than were destroyed by enemy action. Compared with 1938 both notifications and deaths

were down by considerably more than half. The figures the war years were as follows:

		Cases	Deaths
1940	..	46,821	2,480
1941	..	50,791	2,641
1942	..	41,404	1,827
1943	..	34,662	1,371
1944	..	29,949	934

Thus, despite the adverse circumstances of war, something occurred to interfere with the incidence of deaths from diphtheria. What could it be but artificial immunization with the offer of free prophylaxis? The scheme started late in 1941 but did not get properly under way until 1942, and by the end of 1944 children to the number of 5,366,000 had been immunized under local authorities' schemes.

Tuberculosis and Venereal Diseases

The wartime increase in tuberculosis followed the pattern of the earlier years of the last war, but whereas in 1914–18 the tuberculosis death-rate continued to rise until the war ended, in the recent war, from 1942 onwards, there was a small return to pre-war level. Another difference is that in the first world war the greatest proportionate increase occurred among young women; in the second world war it was the older male age groups which suffered most. Although the prima notification figures went up from 35,965 in 1939 to 44,664 in 1944, it is pointed out that these figures are a guide rather than an ascertainment of actual incidence. The use of mass radiography alone makes it likely that there will be increasing notifications of pulmonary tuberculosis during the next few years. The encouraging thing is the favourable trend of infant mortality.

The standardized death-rate for forms of tuberculosis other than respiratory was 129 per million living in 1944—improvement on the earlier war years, but higher than before the war. Sir Wilson Jameson adds:

“Until pasteurization of milk becomes universal throughout the country the most readily preventable forms of tuberculosis, namely those caused by infection with the bovine strain of tubercle bacilli, will continue to cause suffering and death among large numbers of children.”

Social conditions during the war favoured the spread of venereal diseases to a far greater extent than in 1914–18. Families were disrupted as never before, and the country became the training ground for the Forces of other nations as well as our own, so that sexual promiscuity must have been practised on a scale never previously obtaining. In 1939 the incidence of early syphilis, as judged by the cases dealt with at the treatment centres, had reached the lowest point on record, but by the end of 1943 there was an increase in early syphilis (counting the cases dealt with in treatment centres as infections of British Service men said to have been contracted in this country) of about 140% above 1939 figures, followed by a slight decline in 1944. The incidence trends of gonorrhoea are more difficult to calculate owing to the greater tendency of persons with this disease to seek private treatment, but generally it appears that the increase was not so great, that it reached a peak in 1942, when it was about 86% higher than in 1939, and that in 1944 the percentage declined to about 50%. Fortunately there have been potent medicaments available for the treatment of gonorrhoea and now penicillin for both gonorrhoea and syphilis.

Cancer again shows a progressive increase. The postponement of submission of schemes under the Cancer Act has been in one sense fortunate, for a large experience has been accumulated from the approved interim arrangements and a clear conception obtained of an adequate cancer service, which can only be forthcoming where several local authorities pool their resources and secure the co-operation of the large voluntary hospitals.

Emergency Laboratory Service

A section of the report is devoted to the Emergency Public Health Laboratory Service which was set up by the Medical Research Council on behalf of the Ministry. The service now consists of 17 constituent public health laboratories, associated laboratories, and a further 7 in the London sector.

¹ *On the State of the Public Health During Six Years of War. Report of the Chief Medical Officer of the Ministry of Health, 1939–45.* (H. M. Stationery Office; 5s. or 5s. 4d. post free).

has "developed into a valuable instrument in the armamentarium of preventive medicine." It has provided greatly improved diagnostic facilities, has organized field investigations, and has afforded much needed help to overworked medical officers of health. In fact it has become an integral part of the public health service of the country. An important base of its work has been the establishment of reference laboratories, mostly for Vi-agglutination tests and Vi-bacteriophage typing of typhoid bacilli, the serological identification of members of the Salmonella group, the serological typing of aemolytic streptococci, and special chemical investigations in relation to water, milk, food, and sewage.

A hospital pathological service was set up by the E.M.S. and as a result in the extension of diagnostic facilities in the wider field of pathology to hospitals throughout the country. There are now 29 area laboratories as well as a number of subsidiaries.

"The place of the laboratory in the medical services of the future is assured, and it is most desirable that there should be close co-ordination of its three main branches—teaching and research, clinical pathology, and public health bacteriology and epidemiology. Only thus will the laboratory be able to play its full part in the further development of curative and preventive medicine."

As an example of prevention may be mentioned the watch kept on the danger of importation of typhus. So far there have been no cases other than a small number among laboratory workers who contracted the infection in this country. Cases of malaria infected here have also been extremely few—only seven in 1945 and a smaller number in the earlier years—yet there is now a greater risk of indigenous cases occurring.

One of the best organized of all wartime services was the civilian blood transfusion service. Donors on the panels of his service at the end of 1944 numbered over a million. Three main lessons have been learned:

(1) Until a safe and equally effective substitute can be discovered, blood transfusion has come to stay, and the practice of it will increase;

(2) The demand can be met, provided the appropriate organization is available.

(3) Blood and blood products are highly dangerous materials. The dangers can for the most part be avoided, but only by constant supervision by highly skilled personnel.

The advances in this field stimulated by the war will have profound repercussions in civilian practice.

Maternity Care

The maternal death-rate fell almost consistently during the war. It was 3.10 in 1939, and fell gradually to 1.92 by 1944—a rate still too high for complacency, says this report. The decline in the sepsis rate has been even more remarkable. In 1941 deaths from infection during childbirth and the puerperium reached the low level of 0.48 per thousand births, and the decline continued until in 1944 it was 0.28. In 881 maternal deaths in 1944 on which confidential reports were received by the Ministry, sepsis was given as the cause of death in 112, a distinct decline, but deaths from toxæmia numbered 197, an increase on the figures for the preceding years. The other causes to which deaths were assigned were:

Haemorrhage	120	Ectopic gestation ..	13
Embolism	43	Abortion	137
Obstetric shock ..	122	Associated conditions ..	137

The comment is made that with the improved facilities for blood transfusion it is disappointing that the percentage of deaths from haemorrhage and simple abortions remains stationary.

During the war 152,000 mothers were confined in emergency maternity homes in reception areas. In these the maternal death-rate was 0.8 per thousand and the neonatal death-rate 9.6. These figures relate only to normal cases, but among 30,000 confinements in homes upgraded to admit abnormal cases the maternal death-rate was only 1.9 and the neonatal mortality 13.9.

The Emergency Hospital Scheme

Much of what appears in the report about the emergency hospital scheme and the civil defence casualty service was already common knowledge, but it is useful to have it brought

together within a few pages. The story of the organization of beds and medical supplies, the disposal of civilian and Service sick, the arrangements for treating those injured in air raids and the casualties received from the Second Front after D-day is related, and the conclusions to be drawn from this experience are set out. Whatever form the hospital services of the future may take it is believed that the emergency scheme points to the need for the co-operation of hospitals of all types to provide a co-ordinated service for both in-patients and out-patients for an area or region, the provision of specialist centres or units staffed by expert medical practitioners, nurses, orderlies, and others working as teams, and the constant visiting of hospitals by consultants in the different branches of medicine and surgery in order to facilitate interchange of ideas, to stimulate research, and to disseminate knowledge of new methods.

"In peacetime the sudden stresses thrown on certain hospitals are unlikely to occur to anything like the same extent as in war, but even in peacetime occasions may arise when close liaison and pooling of resources would be of great advantage; for instance, in severe local or even widespread epidemics, explosions in factories, fires, mine disasters, or railway accidents."

The emergency scheme grafted on to the existing organization a system of payment for medical staffs for services rendered to the State: first, by creating a cadre of whole-time salaried medical officers of various grades; secondly, by appointing a number of part-time salaried practitioners of consultant rank; and, thirdly, by using the services of other practitioners, both general and specialist, who received fees for rendering such service. It is added that an advantage specially appreciated by the profession was the organization created by the second and third of these classes, under which doctors were able to serve the State to the fullest extent when required, and at the same time carry on their private practices.

The work of the civil defence casualty service is briefly recounted, and the experience gained is held to point to certain conclusions as to the need for rapid and easy transport of accident cases to a hospital competent to provide resuscitation and efficient plenary treatment, for the simplest kind of first-aid treatment on the spot, for an efficient ambulance service operating over wider districts than those of a local authority, for the maintenance in peacetime for use in accident cases of the efficient hospital departments set up to deal with war injuries, and also for the continuance of the revision of instruction in first aid which was found necessary during the war. The experience of the shelters is also the subject of some interesting observations. A section of the shelter population, comprising 4,000 persons, was closely studied from the epidemiological point of view. Nothing which could be described as an epidemic occurred in any of the thirteen shelters concerned, and apart from minor respiratory troubles no outbreak seemed to be related to shelters. The bacteriologists detected many types of pathogenic organisms and watched for the appearance of multiple cases due to any one type, for they were anxious to try out sprays, masks, and other methods designed to control the spread of infection, but no opportunities occurred.

One chapter, too detailed for summary, is given up to a description of a system of random sampling of patients admitted to E.M.S. hospitals with a view to ascertaining the reasons for admission and the average periods of disablement caused by certain illnesses. Thus for appendicitis the median period was 56 days, scarcely affected by the age of the patient; for lobar pneumonia it was 60 days at ages 15-34 and 54 days at ages 35-54; for infective hepatitis 34 and 45 days respectively. The results are set out in a series of tables which are well worth studying.

Finally, the problems of medical manpower as they presented themselves with a varying degree of urgency during the war are set out, including the recruitment of public health medical officers and of general practitioners. A glimpse is given of the working of the civilian medical recruiting boards. These boards altogether carried out over seven million examinations. The time occupied in each examination was on the average just under half an hour, so that the total time spent by the chairman and members of the boards was 3½ million hours, or something like 400 years. Sir Wilson Jamieson pays a tribute to the devotion and endurance of these senior practi-

oners who, without proper rest or holiday, carried on with multitude of tasks, often to breaking point.

The dental and nursing services, the organization of international medical intelligence, and the "push" in health publicity are the subject of separate chapters; and in the last chapter, "Planning for the Future," the various proposals for

National Health Service, from those of the British Medical Association, originally put forward in 1930, are recounted, but the introduction of the Bill now before Parliament is mentioned only in a footnote.

Reports of Societies

PLACING THE TUBERCULOUS IN INDUSTRY

DISCUSSION BY TUBERCULOSIS ASSOCIATION

Dr. NORMAN TATTERSALL presided at the Provincial Meeting at Oxford in July. The discussion on the "Tuberculous in industry" was opened by Dr. F. R. G. HEAF (London). He said that the employer had to measure efficiency in terms of costings and production and at the same time be responsible for the welfare of his staff, infectivity and reduced working capacity making him look upon the employment of the tuberculous with considerable doubt, though feeling a natural desire to help such persons to get suitable work. The age when primary infection occurred was rising, and since 1938 there had been an increase in the proportion of notifications of tuberculosis in higher age groups. The incidence of phthisis was higher in dusty occupations, and even the so-called harmless dusts might indirectly be the cause of spreading tuberculosis by maintaining chronic catarrh in an individual with an undiscovered active lesion. Light work under bad conditions could be more harmful than heavy work under good conditions. Mortality was generally higher in the dusty trades, the peak occurring in the 50-55 age-group, and in the 40-45 age-group in the non-dusty and heavy occupations. As regards disposal, at present it was by trial and error that they determined capacity for work. The allocation to modified work of a person with a stationary minimal lesion, change of occupation, or the continuance of his present job were largely matters of guesswork. An infectious person, diagnosed by mass radiography, might refuse advice, and the authorities could not inform the employers.

The Industrial Medical Officer

The position of the industrial medical officer was anomalous. He might be informed of the number of employees with abnormalities but must not be given the names of persons with tuberculous lesions. A closer link was required between the dispensary, the local labour office, and the welfare unit of each

The Ministry of Labour circular letter 52/46 stated that T.O. must inform the labour office of every tuberculous person under his care who was fit for a measure of employment and required help to find it, and also any case in which the patient might not be fit for work but nevertheless desired advice. The T.O. must also, at the request of the D.R.O., give medical reports on form D.P.1 (X) and advise about work suitable for a particular case.

Mass radiography was best applied to serial examination of those sections of the community in which the risk of contracting tuberculosis was highest. If the Minister were to schedule tuberculosis as an industrial disease, our incomplete knowledge of the pathogenesis would emphasize the need for a national research body. The best plan would be to enhance privileges under Ministry of Health circular 266/T and eliminate the need for proving that the disease was due to the nature of the employment. The relation between management and labour must not be disturbed by special privileges and conditions for a few selected employees. The tuberculous person might be given light work, but he must fulfil his duties. It was best that the patient who had completed treatment but was still sputum-positive should not be re-employed in normal industry; special workshops and close medical supervision were needed.

We were still searching for an easy means of determining the limit of safety of energy output for tuberculous persons; the work of Leitch and Orr on the calories expended per hour in carrying out certain tasks was of value.

Dr. DONALD STEWART (Birmingham) mentioned that there were over 2,000 doctors employed in industry in this country, but that two-thirds of the workers had no industrial medical officer. The situation of the tuberculous could be improved by the collaboration of industrial health and tuberculosis workers, and by the implementation of newer legislation. Mass radiography was valuable, but the difficulty of defining "incapacity" still remained—e.g., dust reticulation. There was need for liaison between tuberculosis officers and local industries, and doctors must know more about their patients' occupations. The T.O. should have access to a placement bureau through the D.R.O.

Occupations for the Tuberculous

There must be special shops for short-period and long-period cases, and they must be centres for retraining, guidance, and the earning of a livelihood. The man who managed the shop was the key to the situation. Pay must be at a weekly rate and not for piece-work. The medical officer who supervised the workers must have that knowledge of machines that would enable him to order "progression through work," and admission and discharge must be his responsibility. Research was needed into the types of occupations suitable for the tuberculous, into the response of such patients to work, their degrees of reserve, and into the economic value of the work which they would do.

Mr. P. GOLDBERG (Ministry of Labour) said that the work of the doctor must be completed by rehabilitation, and that the Disabled Persons (Employment) Act provided for the registration of the disabled, their training and re-employment (many through a quota scheme), and for sheltered employment for the severely disabled. Sheltered workshops were still in the experimental stage, and there were only three at present. There would be perhaps 24,000 employable tuberculous patients out of the registered list, of which about 4,000 would be candidates for sheltered workshops. The quota was inadequate. He envisaged 50 sheltered factories for disabled persons by spring 1947. Where workshops had been opened, applications for registration had come in more quickly. Tuberculous workers were admitted into sheltered factories—some were devoted to them entirely. Hostels and night sanatoria might be provided later. There would be no "driving" of workers; all would be paid an hourly rate based on the best standard regardless of output. Hours would be fixed for each worker on medical advice. There would be a variety of trades and suitable machinery.

In the general discussion, Dr. NORMAN ENGLAND (Oxford) pleaded for proper choice of jobs for the tuberculous, who feared that they might be discriminated against in filling the quota. Dr. J. CRAWFORD (British Legion) hoped that sanatoria might in certain cases get grants to assist their rehabilitation work. There was no place for the tuberculous in heavy industry. Dr. GLYN HUGHES (Wales) emphasized retraining the younger patients (starting in sanatoria with supplementary educational courses) and encouraging them to enter clerical employment.

Dr. W. H. TATTERSALL (Reading) mentioned the difficulty of getting consumptives to register, and of getting the D.R.O. to go to institutions and register them there. He thought that the quota might be invidious. Was it possible under Section 1 of the Act to reserve certain occupations for patients suffering from specific diseases? Dr. A. CAPES (Hants.) demanded a scheme of job-analysis. There should be craft-work and not complete mechanization in workshops. Dr. H. RAMSAY (Walthamstow) said that the T.O. had little time to learn about industrial processes. Dr. R. L. MIDGELEY (Devon) feared that D.R.O.s thought that rehabilitation began only after discharge from the sanatorium. Dr. A. L. JACOBS (London) felt that it was unlikely that all tuberculous patients were registering, and Dr. MOORE (Northumberland) said that many did not wish to register. Dr. J. V. HURFORD (London) asked how part-time workers would get a really adequate wage, even when supplemented by treatment allowances (266/T) or N.H.I. benefits.

● Sanction comes from medical research and official recommendation for the extra-dietetic prescription of vitamins A and D at important physiological epochs and during phases of growth. In practice, many

doctors simply give 'Adexolin' the Glaxo concentrate of vitamins A and D. Guiding considerations are that

Epochal demands of VITAMINS A and D

the vitamin A requirement rises steadily from birth till the age of twenty, that for vitamin D the demand is high in infancy and that the need increases again for both vitamins A and D during pregnancy and lactation. To meet the widest range of demands doctors need only to choose between drop doses of 'Adexolin' liquid or the 3 minim 'Adexolin' capsules.

Capsules: Each capsule contains vitamin A, 4,500 i.u. and vitamin D (calciferol) 900 i.u.
Liquid: Each cc. contains vitamin A, 12,000 i.u. and vitamin D, 2,000 i.u.

ADEXOLIN

VITAMINS A and D. CAPSULES and LIQUID

Capsules: 25, 100 and *1000. Liquid: 1/2 oz., 2 oz., *8 oz.
*Dispensing size only.

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRON 3434

(NIKETHAMIDE B.P.)

Nikethamide has been recommended for use in the treatment of various forms of circulatory collapse, specifically those associated with diabetic coma, acute bronchitis, alcoholic poisoning, and anaphylactic and serum shock. In these, as in many of the most important indications for nikethamide, it is essential to have the drug at hand for immediate use.

Nikethamide is available for clinical use as Anacardone which is issued in solution for injection (Injection of Nikethamide B.P.) and in 25 percent. solution, flavoured, for oral administration. Further details are available on request.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

And E/34

Elastoplast Technique was evolved with 'Elastoplast' Bandages and Dressings. The successful results described in medical and surgical publications were achieved with 'Elastoplast' Bandages and Dressings.

The combination of the particular adhesive spread with the remarkable stretch and regain properties of the woven fabric, together provide the precise degree of compression and grip shown by clinical use to be essential to the successful practice of the technique.

These properties, peculiar to 'Elastoplast', have produced a bandage used for many years with outstanding success by the Medical Profession throughout the world.

Elastoplast
BANDAGES AND PLASTERS

Made in England by T. J. Smith & Nephew Ltd., Hull

REMINDER: Smith & Nephew Plaster of Paris Bandages now carry the universal Trade Mark 'GYPSONA'

Nylon monofilament sutures are strong

Not the least of the many properties of a nylon monofilament suture is its great strength. For instance, a suture of .012" diameter will withstand a pull of some 7 lbs. You can be certain, too, that each succeeding suture will be an exact counterpart of the first. Nylon monofilament sutures are strong, smooth, supple and water resistant, and will remain uninjured by water or steam at the highest temperatures normally used for sterilising. A pattern card can be obtained from your usual Medical Supply House.

IMPERIAL CHEMICAL INDUSTRIES LTD., LONDON, S.W.1

The Successful Treatment of

FIBROSITIS

and certain cases of

RHEUMATISM

with

NOVUTOX

A mass of evidence has accumulated to show that the treatment of Fibrositis and certain cases of Rheumatism with Novutox injections provides not only complete restoration of function with immediate relief from pain, but also, in many cases, early recovery.

Interested members of the medical profession are invited to write for a copy of a Thesis on "THE INJECTION TREATMENT OF FIBROSITIS—with special reference to: Lumbago, Muscular Rheumatism (Acute and Chronic), Muscular Pain (of Traumatic Origin)."

NOVUTOX is available in:

2-oz. and 20-oz. Bottles: $\frac{1}{2}\%$, 1% and 2% Solutions.
Boxes of 12 x 2 c.c. Ampoules: 1% and 2% Solutions.

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl., 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

CHLOROFORM

JAMES YOUNG SIMPSON

OUR association with the manufacture of Chloroform dates back to 1847, when Sir James Young Simpson demonstrated its anaesthetic properties and approached Dr. Thomas Smith (Founder of our Firm) with a view to obtaining

sufficient quantities to carry out his pioneer work.

Our long experience enables us to produce an anaesthetic chloroform of standard composition, UNSURPASSED FOR RELIABILITY, and answering the tests of all pharmacopoeias.

CELLON SERVICE

FOR HEAD LICE

CELETANE (Regd.)

Medicated (Lethane) Hair Oil—N.W.F.

As recommended by the Ministry of Health.
Undetectable in use. Rapidly effective, terminates infection upon treatment.

FOR SCABIES

BENZELIA (Regd.)

Benzyl Benzoate—25%

An emulsion of high efficiency, containing 2% Sodium Lauryl Sulphate, which is extremely effective in the treatment of this infestation. Complete eradication of Scabies is effected within 24 to 48 hours.

Further information, samples and prices upon request.

Danger of Discontinuous Treatment

Dr. F. R. G. HEAF feared that the patient might be split between two authorities, the Ministry of Health for treatment and the Ministry of Labour for employment. Rehabilitation must be merely continued treatment and the case sheet start in the sanatorium. There was a risk of the disabled worker sheltering behind the shadow of his chest. Dr. STEWART said that with good management the less healthy person might be carried along in the team. He advocated a chain of workshops for the tuberculous, and courses in industrial medicine in the universities.

Mr. GOLDBERG said that no Ministry could be responsible for the diversional therapy in sanatoria. A sheltered workshop run in conjunction with a sanatorium would be grant-aided. There was no intention to abolish craft-work. If the patient worked for a full week in the special shop, even if he gave only 20% of a normal output, he earned a full weekly wage, but for 20 hours in the shop he would get hour-rates. Supplementation must come from elsewhere.

Mr. GOMME (Ministry of Labour) said that in engaging workers for employment, whether under the quota or otherwise, the last word rested with employers. Registration at sanatoria was inadvisable, especially as many in-patients would be away from their home areas. However, the D.R.O. might advise patients. An employment could not be "designated" for a specific disease. Job-analysis research was being sponsored by the British Council of Rehabilitation. Local authorities were subject to quota obligation. Registration must be voluntary.

ASSOCIATION OF CLINICAL PATHOLOGISTS

The summer meeting of the Association of Clinical Pathologists was held at Oxford on July 26 and 27, and lectures and demonstrations were given to a large audience. Dr. WINSTONE EVANS opened the proceedings with a paper on "Observations on Sickle Cell Anaemia" based on his West African experiences. Sternal marrow from twenty cases showed that no specific changes were present in the early cells and only occasionally in reticulocytes and normoblasts—i.e., sickle-ing only took place with ease after the loss of the nucleus. Sealed moist preparations showed a typical expansion, tenseness, and filamentous extensions six to eight hours before sickle-ing, and then an explosive onset. Of six hundred males subjected to routine testing there was an over-all incidence in fit soldiers of 19.9%, with the highest in the Gambians of 30%. Almost anything could occur in the clinical picture of sickle cell anaemia, including leg ulceration, and the sickle-ing was really not the primary lesion but merely a side-show superadded on other diseases. Several pathologists who had served in Africa agreed that the oxidation-reduction was the important factor producing sickle-ing in ten to fifteen minutes, whereas alteration in pH alone showed no changes.

Dr. E. JACOBSEN from Copenhagen showed that if reticulocytes were kept in saline at 40° C. there was no drop in their number in six hours, whereas when liver was added ripening of the reticulocytes took place very quickly. He divided the liver principle into two parts: a thermolabile fraction absorbed by florodin, and a thermostable part not absorbed. The thermolabile portion was a xanthine of which folic acid was probably a part. Stomach tissue also contained a good deal of the thermolabile fraction. Organs of different animals had different amounts of ripening substance; those with low normal reticulocytes having the highest ripening value and those with normally high reticulocytes having low value. Increased reticulocytosis might therefore not necessarily mean an increased output from the bone marrow but might mean a decrease in the ripening factor. Dr. B. MALAMOS from Greece then surveyed Cooley's anaemia as it occurred in Greece.

Dr. S. WRAY read a paper on "Acid Phosphatase" based on 25 cases of prostatic carcinoma. After describing the technique for estimation of acid phosphatase and its increase in prostatic carcinoma, he showed tables suggesting that maintenance doses of oestrogens would probably be necessary for the rest of the patient's life, and showed histological sections of degeneration in secondary deposits.

Errors in Haemoglobinometry

A discussion then started on the reliability of clinical haemoglobinometry, and Dr. MACFARLANE showed how in a series of investigations on the significant error in haemoglobin estimations a 20% difference between two examiners had occurred. The investigation allowed for the usual errors; heparinized blood was employed, and sixteen methods were used on sixteen samples of blood by sixteen observers. The observations showed no real agreement between the different methods as compared with the base line of the National Physical Laboratory, in which iron estimations on the method of King were used. The final conclusions on the significant error were that reported differences of 4% were significant with any one observer and 5% with any two observers. Dr. WOOTTON showed that colorimetric methods were nearer the results obtained with iron estimations than were those by gas analysis, and suggested that grey wedges should be used, calibrated directly in grammes of haemoglobin. Dr. MacFarlane then suggested that the original N.P.L. standard of 13.8 was too low and that we should now accept 14.7 grammes % as the standard 100% haemoglobin. In the demonstrations these workers put up twenty-seven methods of estimating haemoglobin, starting with the Talquist paper and ending with the photo-electric haemoglobinometer, and many members of the audience read the different samples in the different machines, demonstrating a very wide scatter in their readings.

Homologous Serum Jaundice

Dr. JANET VAUGHAN followed with a paper on "The Incidence of Homologous Serum Jaundice after Transfusion," based on cases from the N.W. London Transfusion Depot. The follow-up was done five months after transfusion. A report to the Medical Research Council, by Dr. Vaughan and two of her colleagues, on the incidence, incubation period, and symptomatology of homologous serum jaundice appears in the opening pages of this issue of the *Journal*.

There were many excellent demonstrations, and the meeting ended with a paper by Dr. A. MEKLEJOHN on "Silicosis."

At the last meeting of the Council of the Liverpool Medical Institution, the President, Dr. G. F. Rawdon Smith, intimated that the following had accepted Honorary Membership of the Institution: Alfred Ernest Barclay, M.D., F.R.C.P., Sir W. Allen Dalry, M.D., F.R.C.P., Dame Louise McIlroy, M.D., F.R.C.P., F.R.C.O.G., Charles McNeil, M.D., F.R.C.P., Ivan Whiteside Magill, M.B., B.Ch., D.A., Sir Alfred Webb-Johnson, Bt., P.R.C.S. The Honorary Memberships will be conferred at a special general meeting of the members of the Institution on Saturday, Oct. 19.

TRAVELLING FELLOWSHIPS IN MEDICINE

The Medical Research Council announces that it has awarded Rockefeller Medical Fellowships to the following, for the academic year 1946-7:

Sheila Theodora Elsie Callender, M.D., B.Sc., M.R.C.P., graduate assistant, Nuffield Department of Clinical Medicine, Oxford.

Charles Enrique Dent, Ph.D., M.B., B.Sc., M.R.C.P., research assistant, Medical Unit, University College Hospital, London.

Arthur Morgan Jones, M.Sc., M.B., M.R.C.P., Leverhulme Research Scholar (Royal College of Physicians), University and Royal Infirmary, Manchester.

Alistair Mitchell MacDonald, M.D., F.R.C.P.E., Department of Pathology, Edinburgh University.

John Edgar Morison, M.D., B.Sc., lecturer in morbid anatomy, Queen's University, Belfast.

Francis Thomas Carnet Prunty, M.D., M.R.C.P., lecturer in chemical pathology, St. Thomas's Hospital Medical School, London.

Francis Felix Rundle, M.D., B.Sc., F.R.C.S., surgical specialist, R.A.M.C., lately chief assistant and registrar, Westminster Hospital, London.

John Swanney, M.C., M.D., M.S., assistant surgeon, Department of Urological Surgery, Newcastle-on-Tyne General Hospital.

The Council has also awarded a Dorothy Temple Cross Research Fellowship in Tuberculosis to Thomas Francis Jarman, M.D., assistant tuberculosis physician, Welsh National Memorial Association.

Correspondence

Classification of Psychological Disorders

SIR,—There is so much variety in the classification and nomenclature of psychological disorders that argument and discussion about psychiatric problems easily become confused unless the participants take care to be precise in defining their terminology. The interesting paper by Dr. Sands in your issue of Aug. 31 would, I think, have gained much if he had done so. Under the heading Anxiety Neurosis, for example, he writes: "There is every likelihood of doing more harm than good in attempting to treat anxiety states with E.C.T." What is Dr. Sands's definition of an anxiety state? In descriptive terminology this should mean a state of anxiety, and this is what it does mean to many psychiatrists, but from the heading which governs the sentence I have quoted it appears that anxiety state is for Dr. Sands synonymous with anxiety neurosis. If so the reader should know what is his definition of neurosis. From some of his statements one might conclude that his distinction between neurosis and psychosis is that in the former the affective disorder is reactive and in the latter endogenous. This would be a conventional and intelligible distinction in terms of aetiology (instead of symptoms) and applied to the paragraph under discussion would mean that E.C.T. is of no value for reactive anxiety states, leaving open the question of its value for endogenous anxiety states. But Table V includes reactive depressions among "mild or moderately severe psychotic cases." Does Dr. Sands mean that depression whether endogenous or reactive is a psychotic symptom and anxiety a neurotic symptom?

In Table III he produces figures to show that E.C.T. gives better results in depression with anxiety than in anxiety neurosis, but I find it difficult to discover from his paper what precisely is his distinction between the two. It is presumably not symptomatic because he states that anxiety and depression are to be found in both. If aetiological, the distinction is not made clear. A third possibility is suggested by a sentence in his discussion of differential diagnosis in relation to E.C.T. which reads as follows: "The truth is that in this direction treatment has outstripped diagnosis and is likely to be more accurate than the clinician." This statement I find obscure, but it looks as if it might mean that the best criterion for diagnosis is the response to E.C.T. and that if a case previously diagnosed anxiety neurosis responded to this treatment the diagnosis might be altered to depression with anxiety.

I see no objection to the classification of psychological disorders in terms either of symptoms, aetiology, or response to specific treatment so long as each method of classification is clearly and separately defined, but it seems to me that in this paper, as in many other contributions to psychiatric literature, these different kinds of classification are confused, with the result that the data and conclusions are deprived of much of their value.—I am, etc.,

London, W 1

C. P. SYMONDS.

Painful-feet Syndrome

SIR,—I have read with considerable interest the article (Aug. 24, p. 260) entitled "Painful-feet Syndrome among Prisoners of War in the Far East," by J. A. Page. As a medical specialist in the main P.O.W. hospital, Singapore, my time and thoughts were exercised to the full by the outbreak of this syndrome among many hundreds of our fellow-prisoners five to six months after our capture. The syndrome was preceded by manifestations of vitamin B deficiency—lesions of the mouth, tongue, lips, and scrotum attributable to deficiencies of B₂ factors, and later the dermal lesions which have given the pellagra syndrome its name. At about the time of its onset retrobulbar neuritis began to occur frequently, and in much smaller numbers a form of keratitis which we termed granular cornea. I observed no constant vascular or neurological changes except tenderness of the soles on pressure. Redness of the feet could usually be explained by the constant massage to which they were subjected. Increase of the knee- and ankle-jerks was found in a number, but this was probably

evidence of the beginning of our next deficiency syndrome, which manifested itself by signs of pyramidal system disorder.

The author's description of the early clinical picture coincides with that seen in Singapore with the exception of the change in the tendon reflexes. I submit that the later signs were dependent upon climatic conditions. Our chronic cases continued in the same state for many weeks or months, perhaps developing other of the deficiency syndromes such as retrobulbar neuritis or a spastic paraplegia, but never cyanosis of the limbs, gangrene, etc. Under the heading of discussion the author mentions that in the later months of 1942 many of the cases were complicated by the nerve lesions of pellagra. I assume that these lesions would include evidence of pyramidal system involvement resulting in spastic paraplegia.

As regards the nature of the painful-feet syndrome, the only references I could find in 1942 were Kingsbury's report in Manson's *Tropical Diseases* and an account by Pallister in the *Journal of the Malaya Branch of the B.M.A.*, September, 1940. The most significant reference to my mind was the following from the description of pellagra in Manson's textbook: "Another characteristic symptom is a feeling of burning in the palms of the hands and soles of the feet." The syndrome under discussion is that of painful feet, but burning feet was frequently used as an alternative description in our camp, and a small proportion of the severe cases suffered the pains in their hands as well. This led me to believe that the syndrome was probably part of the pellagra symptom complex, and I started using nicotinic acid in the form of "coramine," "nicamide," and nikethamide for its alleviation. The results were most satisfactory and dramatic in the majority of cases. The dosage finally decided upon was 1.7 ml. intravenously twice daily for five days. In successful cases improvement started within three days.

Many cases were treated as out-patients, but unfortunately I have no records of them. Of one hundred and seven hospital case records which I extracted eighty-eight received "nicotinic acid" with the following results: Cured, 33 (37.3%). Very much improved, 26 (29.5%). Better, 25 (29%). No improvement, 2. No record of result, 2. Relapses occurred some weeks later in some cases, as there was no improvement in the diet.

As only indifferent results were obtained in Page's cases from nicotinic acid therapy it would be of interest to know the dose and method of administration tried.

One other point of interest: a battle casualty who had lost one leg by amputation through the thigh had pains in both feet.—I am, etc.,

Chester.

PHILIP R. GRAVES.

Problems of Pneumoconiosis

SIR,—In the *Journal* of Aug. 31 (p. 301) there appeared a leader on the very important subject of "Assessment of Disability in Dust Diseases of the Lung." In the final paragraph of this an ill-advised personal boost was given to the distinguished director of the Medical Research Council's unit in South Wales. This has been accompanied in the national daily press by further journalistic fantasy. No doubt the distinguished director is fully aware of all the difficulties, but my former colleagues of the Medical Board for Silicosis and Asbestosis who have been most intimately associated with this problem have been perhaps even more keenly aware of these difficulties—and for a considerably longer period of years. The designation "benign pneumoconiosis" is not new and was current before 1945.

Under the present system of workmen's compensation the workman, when injured by a compensatable accident or disease, is not entitled to compensation for the injury as such or for disability arising therefrom but only for loss of earning capacity, and even then not for the whole loss. So far as the pneumoconioses are concerned, compensation in respect of death, total disablement, or suspension is restricted to workmen engaged in certain defined industries and processes (and these workmen only) as provided for in special schemes. On what evidence of authority can your writer assert that "the assessment of disability . . . at present is decided largely by radiographic appearances," or again that "many men with reticulation who are not disabled are obtaining disablement certificates"? One can only assume that this refers to official certificates under the schemes. If so, this involves a serious criticism of the Chief

lical Officer and other members of the statutory Medical Board for Silicosis and Asbestosis. Hart and Aslett may have pressed the opinion that only a "small proportion of these emulsion cases were significantly disabled," but they were not necessarily right and the Medical Board wrong. In any case the Medical Board are not required to certify whether the workman is significantly disabled. If they grant a certificate it must be completed in the prescribed form and in accordance with the marginal directions without ifs and buts and such qualifying adverbs as "significantly" or "substantially." In any case, they may and do certify in certain cases that the workman's general physical capacity for work by reason of the disease is not impaired.

There are many other serious inconsistencies and anomalies in the subjective commentaries, reflecting a lack of intimate personal experience of the compensation problems and the rationale of the schemes. The assessment of disability is a difficult problem, but even more urgent is the natural history of dust reticulosis in coal miners. Is it merely a dust tattooing of the lungs? Is it progressive? Is it a disease, benign or otherwise?

In conclusion I venture to wonder how long we must wait before those responsible for directing researches will recognize that in clinical investigations the field workers have a substantial contribution to make in the course of their routine work. Is their experience for naught, simply to be passed to the care of others, while they, the field workers, are reduced to the idleness of compiling official records and certificates and to suffering in silence derogatory comparison and anonymous criticism?—I am, etc.,

Glasgow, N.W.

A. MEIKLEJOHN.

Pathogenesis of Cancer

SIR,—The "Hypothesis on the Pathogeny of Cancer" written in 1927 by your correspondent (Aug. 31, p. 311) A. Curies and Agua was anticipated at least twenty years earlier by Blair H. who, investigating the effect of lead in cases of chorion epithelioma, attributed the disease to the death of the foetus *in utero* and consequent removal of the "endogenous stimulus." I am, etc.,

Quincy Heath, S.W.15.

SARAH WINSTEDT.

Oestrogens and Prostatic Carcinoma. Transurethral Prostatectomy

SIR,—I should like to clarify and add to my remarks with reference to the relative potency of stilboestrol and dienoestrol in the treatment of carcinoma of the prostate (Aug. 10, p. 191). The statement that dienoestrol is three times as active oestrogenically as stilboestrol was made in a personal letter from the manufacturers or central distributors. I am now informed from the highest authority that this statement is not clinically correct. The side-effects, however, with dienoestrol have, in my experience, been much less in evidence than with stilboestrol. Mr. Terence Millin refers in his letter (Aug. 31, p. 309) to the "inaccurate figures and erroneous conclusions" contained in my letter (Aug. 17, p. 241) and gives his total for transurethral prostatectomy operations on the prostate as over 1,600. I had attributed to him a total of 219 cases. The figure of 219 was taken from a table in his paper (*Proc. roy. Soc. Med.*) which is described as "showing my own results where a selection of methods was employed." In the absence of any reference in his paper to any series where a selection of cases was not employed, I concluded that it had been his routine practice to employ such a selection of methods. It is now evident that Mr. Millin intended to convey the idea that this table referred to a particular group, distinct from a much larger group comprising approximately 1,400 transurethral resections. In searching his paper for any reference to the existence of this larger group I have only been able to find the statement "in my last 30 cases I lost 8. I have had better series, etc." Noting his use of the word "better" (rather than larger) it appeared to me that this 30 was included in his figure of 219. It is on these points that the misunderstanding has arisen. After re-reading his paper, I can only admit that the facts and conclusions contained in my letter were understandable interpretations of elliptical statements.

My support is for transurethral prostatectomy with the cold punch. It was only after my change over from the diathermy

loop to the cold punch that transurethral prostatectomy successfully challenged abdominal prostatectomy. Mr. Millin's transurethral resections have mainly been carried out with the diathermy loop.—I am, etc.,

Manchester.

H. T. COX.

Tobacco and Ulcer Dyspepsia

SIR,—The article by Mr. R. A. Jamieson, Prof. C. F. W. Illingworth, and Dr. L. D. W. Scott under this heading (Aug. 31, p. 287) is of great interest to many, like myself, who have given up the use of tobacco because of indigestion. In my personal experience cigarette smoking invariably brings flatulence, heartburn, and eventually actual pain in its wake; pipe smoking is followed by none of these symptoms.

Is it not possible that the difference lies not in the actual absorption of the drug in the two types of smoking, but that in cigarette smoking the smoke itself irritates nerve endings in the upper respiratory passages, thereby causing reflex pylorospasm? This interferes with the normal reflex of chyme from the duodenum, with the result that acid accumulates in the stomach, producing acidity and heartburn. When the pylorus does relax an accumulation of acid is expelled into the duodenum, thereby aggravating a pre-existing ulcer or possibly even producing one.

It is not necessary to be a heavy smoker for these symptoms to arise; a few cigarettes daily will produce irritability of the pylorus, hence the fact that heavy smoking does not make a great difference. I think this theory would also explain the great benefit derived by this type of dyspeptic from a mixture containing belladonna and soluble phenobarbitone.—I am, etc.,

Tavistock.

T. M. DAVIE.

Effects of Tobacco

SIR,—Before the war I vaguely subscribed to the belief that the use and especially the abuse of tobacco were harmful in varying degrees at least to the digestive and cardiovascular systems. Five years of work in British general hospitals overseas have given me ample opportunity to observe a large population smoking to excess, and in many cases to gross excess. Sixty cigarettes a day was a common consumption, and not a few confessed to eighty or more. Yet even with this bias of preconceived opinion I was unable to ascribe with confidence, a persistent cough, a bout of dyspepsia, or even an extra systole to the harmful effects of tobacco. This still seems to me remarkable, and no less so when one recollects the various foul brands of unfamiliar name which at times were smoked *faute de mieux*.

The recent paper by Prof. Illingworth and his colleagues (Aug. 31, p. 288) indicates that no case can be made out against tobacco even in the presence of ulcer dyspepsia. But although it has not been shown to be a cause of organic change, there is no doubt that it affects, functionally at least, the respiratory system. While smoking shallow breathing is the rule, and "chain smokers" have a constant functional reduction of vital capacity. This "poor wind" is very noticeable in those who smoke while engaging in physical work, a habit which has become widespread during the war.—I am, etc.,

Glasgow.

JOHN FLEMING.

Smallpox in the Vaccinated

SIR,—I feel I cannot let paragraph two of Dr. C. Killick Millard's letter (Aug. 24, p. 274) pass without comment. Dr. Millard states: "The failure of successful revaccination to protect completely for even eighteen months is certainly surprising and rather disquieting... and affords a warning against over-confidence in its efficacy." To me it means only one conclusion, that the man in question was inadequately revaccinated in 1942.

The Army Forces were vaccinated by one scarification only until 1944, after which the Army Order came into force whereby three scarifications were made, one a control. Why this change? I can only surmise because the Army authorities experienced much modified smallpox in the Middle East and India, causing them to realize that personnel were not adequately protected by one scarification only. This being the case the originator of the outbreak of smallpox in Middlesex during 1944 would have been revaccinated with one scarification in 1942, and to me it

is by no means surprising that in contact with smallpox in 1944 he developed a modified attack. Why then should the efficiency of vaccination be in doubt? Surely the fault lies with us in inadequate vaccination; we expect too much from one scarification. If I may use a simile—should one cease the treatment of gonorrhoea with sulphathiazole because we have found that with a dose of one tablet t.d.s. we cannot cure this disease? Or should one lose faith in the efficacy of T.A.B. vaccine for the prevention of typhoid when we find that 0.5 ml. fails to protect the patient?

In my letter (June 8, p. 889) it will be noted that of the four cases of smallpox reported three were modified, and subsequently a fifth case developed, also modified in type; surely a very high percentage, and the only conclusion we can come to is that these men were inadequately vaccinated. In October, 1944, I vaccinated a member of the crew who bore good marks from vaccination in infancy, and who had been unsuccessfully vaccinated in 1939, 1940, 1941, and 1942. I used one scarification only, and the result was a very severe take. The person in question ran a temperature of 104° F. (40° C.) for three days, and the arm took five or six weeks to heal, leaving a scar the size of half a crown. This man, along with the rest of the crew, was revaccinated on Mar. 1, 1946, some eighteen months later, and I used three scarifications, and rather to my surprise all three took well. This proved to me that I had inadequately vaccinated the man in 1944, and had he been exposed to smallpox I should not have been surprised had he developed a modified attack.

I am quite sure it is time that we realized that vaccination will not protect for seven years; I doubt if it protects for much more than two years. Once more, Sir, may I stress what I consider in these days a most important point, namely, that when we vaccinate we should vaccinate adequately, particularly those whose journeys take them to or bring them from countries where smallpox is endemic.—I am, etc.,

London, S.W. 1.

F. K. BEAUMONT.

Food-poisoning in Boston

SIR,—In the note about the recent outbreak of food-poisoning in Boston, Lincolnshire (Epidemiological Notes, Aug. 31, p. 316), it is stated that "*Salmonella typhi-murium* has been isolated from the stools of notified cases but not from the ingredients of the ice-cream." Although this statement is true, it might prove misleading by implying that the organism was not isolated from the ice-cream. *Salmonella typhi-murium* of the same phage type was in fact first isolated from the ice-cream before being isolated from the stools.—I am, etc.,

Lincoln.

J. M. CROLL.

Artificial Leg for Women

SIR,—I wish to raise the question of designing an artificial leg really suitable for a woman. I do not know what the proportion of one-legged women to one-legged men is to-day, but I should imagine it is not far off 1 to 2, and that it is increasing; not only did the war leave us a legacy of many women who had lost a leg in air raids or in one or other of the Services, but also there are road accidents which are no respecters of sex, and, with more women in industry, more may be crippled at work. In spite of this, however, there is still no artificial leg made which is specially designed for use by women.

I have thought this for a long time, but I am moved to write to you on the matter because I have just had a letter from a young woman, an art student, who lost a leg in an accident some two years ago and has now at last been fitted with an artificial leg. Although she is quite pleased with the limb and is very glad to be walking on two legs again after so long on crutches, so that she can now go out without, as she puts it, "being the object of that embarrassing attention that the passer-by accords to every one-legged woman on crutches," she is nevertheless disappointed in some respects. She makes certain criticisms—some mechanical, some cosmetic. Her first complaint is the range of movement possible at the hip; she has a perfect hip-joint and her thigh stump is ten inches long, yet the limb is so attached and slung that without feeling insecure she cannot abduct her limb at all, and movement is virtually limited to pendular to-and-fro action only. She was

told before she had her artificial leg that it would let her dance, but with this limitation dancing is practically impossible; men, on the other hand, she finds out, are fitted with a different type of suspension, which allows full abduction; so enables even above-knee amputees to dance. This suspension apparently is never given to women as it is somewhat bulky and shows under their clothes. Surely, she asks, at some time some limb-maker designed a suspension allowing a movement which could be worn under a woman's clothes.

The next criticism is that the standard shape of the socket is triangular; this is well suited to the more angular stumps of men, but women amputees, particularly a little fat, like my friend, have rounded stumps. In consequence, as she points out, her limb tends to slip round on her stump, which upsets her walking altogether. This seems a small point to correct, but it is probably a question of going against preconceived ideas.

Her next point is the way the foot is attached to the shin piece; this is done at a definite angle depending on the height of heel it is wished to wear, but the ankle movement is limited that there is very little latitude possible in height of heel. If a woman wishes to wear a one-inch heel during the day and say a 2½- or 3-inch heel in the evening, she must have two different artificial legs, one for each height of heel. Is not possible to design a limb which incorporates some simple adjustment for heel height? My friend tried wearing a high heel than her limb was designed for, and found it nearly threw her on her face; so this is not, as she says, "just a bit sales-talk."

On the cosmetic side her criticism is chiefly that the standard shin is made to the conformation of a man's leg irrespective of whether the leg is for a man or a woman, so even at the knee and stockinged a woman's artificial leg is always obvious. The measurements are the same for the artificial shin as for the natural one, but the shaping is all wrong; thus the calyx of a woman's calf is quite missed. She makes the interesting suggestion that the shin-piece of an artificial leg for a woman should be made not of shaped metal, but that support should be given by a simple metal tube round which is built in section a properly shaped leg carved out of some very light wood such as balsa. The finish of the leg also leaves much to be desired; she has to wear two stockings to prevent the hard metal glitter showing through, and even then in strong sun there some shine visible.

Her last point is the knee; it is not the right shape for a man or a woman, being too rounded and symmetrical. These days, she insists, no woman keeps her knees always hidden without being conspicuous. For women's limbs, at least, better modelling of the knees is required. The lines of the joint itself she supposes cannot be made less marked than they are.

It seems to me, though I have no first-hand knowledge of artificial legs, that most of my friend's criticisms are probably justified; in any case I pass them on to you for ventilation in the *Journal*.—With your permission I sign myself

"L.S.S.W."

Hypersomnia with Abnormal Hunger

SIR,—I was most interested to read Dr. James Ronald's excellent article on hypersomnia associated with abnormal hunger (Sept. 7, p. 326). Now that attention has again been drawn to this rare syndrome it is to be hoped that further accounts will be forthcoming from other sources. The cases which Dr. Ronald mentions resemble in almost every respect those described by Dr. Critchley and myself in the *Journal* of Jan. 31, 1942. Dr. Ronald states, however, that in his case "An electroencephalogram revealed no abnormality, and that it is in accordance with the findings of Critchley and Hoffman." In actual fact our first case did show an abnormal E.E.G. Although the resting rhythm was normal, overbreathing evoked a large intermittent delta discharge in both frontal lobes, but this was more regular on the left. No conclusions were drawn regarding the significance of this finding. I am not aware of other cases of the syndrome which showed similar tracings, but in my own experience abnormal E.E.G.s are occasionally found in narcolepsy.—I am, etc.,

Bath.

H. LOVELL HOFFMAN.

Supplementing the Harvest

Our main source of vitamin B₁—wheat—being restricted, "normal diet" may not always supply enough of the vitamin to meet the extra demands of convalescence and of pregnancy and lactation.

Common symptoms of hypovitaminosis are: dyspnoea on exertion, anorexia, atony of the bowel, and mild paraesthesiae.

Rapid improvement often follows treatment with synthetic vitamin B₁. Oral treatment—continued for some time after the symptoms have disappeared—is usually adequate.

STILBOESTROL and related SYNTHETIC OESTROGENS

Every medical practitioner should send for a copy of "Stilboestrol and Related Synthetic Oestrogens"—a 32-page manual compiled by the scientific staff of Clinical Products Ltd.

This manual is designed to give quick, easy access to available data on these important substances, and covers the significant works of leading investigators in the field of Stilboestrol research.

Menopax preparations—both the tablets and the anti-pruritic cream—are in constant and ever-increasing production to meet demand. Free medical samples and a copy of this book (to satisfy Paper Regulations please send one penny stamp) will be gladly forwarded on application to:—

Clinical Products Ltd.,
Richmond, Surrey.

"... a complete
guide to the
applications of
synthetic oestrogens
in clinical
practice."

For Gastric or Duodenal Ulcer

IN view of the increasing adoption of intensive alkaline medication for gastric and duodenal ulceration, the selection of a suitable antacid agent is a matter of considerable importance to the general practitioner.

'Alocol' allows of antacid therapy in a particularly effective, safe and reliable form, and replaces with advantage mixtures of sodium bicarbonate, magnesia, bismuth, etc. It does not produce any unpleasant secondary reactions, even when taken in strong doses and over a long period of time.

'Alocol' neutralises excess gastric acidity to the most favourable degree without provoking the danger of alkalosis, thus producing a markedly soothing effect on the gastric mucosa, with the prompt relief of pain and discomfort.

'Alocol' is available in Powder and Tablet form.
Powder—The normal dose is 1 gramme before and after meals

Tablets—Each tablet contains Alocol, 0.5 gm.; P. Sacch. Alb., 0.4 gm.; Cocoa Powder, 0.035 gm.; Excipient, q.s. The normal dose is 2 tablets before and after meals.

ALOCOL

Colloidal Aluminium Hydroxide

Complete chemical history of 'Alocol' with convincing clinical reports and supply for trial sent free to physicians on request

Recurrent Inguinal Hernia

SIR,—With reference to the particular point of dealing with the radical removal of the hernial sac, forming part of Sir Ernest Cowell's memorandum (Sept. 7, p. 330), I find most satisfactory control to be achieved by passing a hernia-needle, guided by a forefinger, in through the opening where the sac was; sliding the point along the inside of the peritoneum upwards and out through the abdominal muscles to present back into the upper part of the wound. I use it to withdraw inwards and then out through the sac mouth fifteen inches of chromic gut, the lower end of which is used to suture the peritoneal opening, which after suture is inverted upwards and anchored well away from the hernial site by pulling on the other end of the catgut. This is then itself used to close the gap between the muscles and Poupart's ligament, this union being, during healing time, automatically drawn tighter by the very cough which would otherwise tend to thrust sutured peritoneum into newly repaired internal ring. I have used the method for fourteen years.—I am, etc.,

Ferth.

ROBERT NAPIER.

Serous Pleural Effusion

SIR,—In your leader on serous pleural effusion (Sept. 7, p. 333) I was sorry to see no reference to perhaps the most important contribution on the subject. I refer to Dr. Brian Thompson's paper to the Tuberculosis Association in May of this year. This paper is summarized in the Association's abstracts. Thompson's cases numbered 190, and of these only one patient was lost sight of, and he had emigrated to Canada; of the remaining 189, no less than 25% developed phthisis within five years, while 3.5% died.—I am, etc.,

Edware.

STEPHEN HALL.

Health Service Bill

SIR,—The five major points of disagreement between Government and the profession are: (1) *Direction*, i.e., requirement of seeking sanction of the Service. (2) Rendering doctors in the Service liable to dismissal with *no right of appeal*. This putting of persons absolutely in the hands of a Government department is the essence of the loss of civil freedom. In these matters doctors are only a chance group of the nation on whom the proposed restrictions are first to be placed. These features concern our rights as citizens, not as doctors; we must resist these. (3) The question of *ownership of practices by Government*, and (4) *basic salary*, are in a different category. There is less unanimity in the profession about these, and I believe accommodation may be possible here. As to (5) *the State owning all the hospitals*, it seems that matters have moved too far to be reversed. Willing support has already been diminished: damage has been done irretrievably. Further, there is among specialists and consultants a view rather favourable than opposed to these Government plans.

The following proposals are submitted as a possible means of avoiding tragic conflict which, even if it does some good, will surely bring harm in its train through bitter words and misjudgments. (a) Government to give way on the right of appeal and direction of doctors. (b) The profession to give up its opposition to the hospitals plan. (c) Government to undertake to suspend for eight years the ideas of purchasing all practices, of prohibition of sale of practices, and of basic salary. During this period the profession shall work the new Service and arrange matters so that all parts of the country are fairly supplied with general practitioners without having recourse to direction. The profession, on its part, to undertake that, if at the end of the time there is any question as to the satisfactory distribution of doctors, it will refrain from opposing the putting into operation of the present Bill's proposals; subject of course to necessary financial alterations consequent on changed conditions. Government to undertake that if distribution of doctors be satisfactorily accomplished it will repeat the present objectionable features.

During this period a scheme, other than basic salary for all, would be tried out with the official help of the profession: the profession would also implement its frequently expressed ability to arrange for young doctors to buy practices without intolerable financial burdens. These two aspects would

necessarily mean official financial backing by the profession. Government would naturally retain the right (similar to that in the N.H.I. Acts, and that proposed in Section 43 of the present Bill) to take any necessary action in bad spots.

Should some such compromise be adopted two immense gains would accrue: An open road for negotiations to take place on the numerous less fundamental points of disagreement which are probably capable of arrangement; and a changed prospect before the new National Health Service from one of grudging acquiescence by a discontented profession into cordial co-operation.—I am, etc.,

Luton.

B. RANDALL VICKERS.

SIR,—As a profession we stand in a unique and peculiarly responsible position towards our fellow men and women. We have an inescapable duty towards them, and it is high time to stop timid appeasement and act unitedly with courage and determination. The issue is plain. Dr. Waddell has gone into details in his admirable letter (Sept. 7).

This Health Service Bill is fundamentally dishonest: towards the voluntary hospitals, towards the medical profession, and towards the people of England. It is really a political measure to ensure control by a bureaucratic tyranny, i.e., by a totalitarian State. Recently a Socialist M.P. told a friend of mine that this Government intends to take control of the medical profession first, because it is by far the most important one, and has the most power over the people. After that, he said, it will be easy to take control of the other professions, one after the other. Our duty is plain: We must oppose this with all our might. Whether we like it or not we are now the guardians of English freedom and individual responsibility. We must say no quite categorically and with no reservations whatever to the whole Health Bill. But if it passes, as with the Government's large majority it very probably will, our duty is still clear. We must make it a dead letter. We must of course treat our patients as usual but must refuse to sign any certificates whatever. This will involve hardship, probably to many thousands, but only for a short time. The Act will be dead in less than a month.—I am, etc.,

Winchester.

SYBIL TREMELLEN.

SIR,—Like most doctors we are in favour of a State Medical Service, and endeavoured to assess the new Bill in the light of its merits as a medical measure. Seen as such, it has much to commend it. Unfortunately the question is not so simple, and it was only when we realized that larger and more important issues are involved that we modified our first impressions, and ultimately came to a definite decision that the Bill must be opposed at all costs.

Individual freedom is rapidly disappearing in this country. The new Health Bill is a severe blow to what remains of the liberty of the individual for the following reasons: (1) It is compulsory. All must contribute to it. No doctor will be able to exist outside it. (2) The preventing of an Englishman from working where he chooses in England is an entirely new restriction and a very serious matter. (3) Not since mediæval times has anyone had power in this country to dismiss an Englishman from his job and prevent him from obtaining another job in his profession. (4) Never since Magna Carta has anyone been able to refuse an Englishman the fundamental civil right of appeal to the High Court.

Why did Mr. Bevan so strenuously oppose the very reasonable request that we should keep the right of appeal? Because he knows that English judges are still fair and unbiased, and if appeal to them were allowed he would not have the absolute control over the profession which is obviously his aim. These are only a few of the fetters which, if we agree to work the Bill, will be fastened on us and from which we shall never escape. Even at this late moment we still have the choice between submitting to the dictates of Mr. Bevan or striking a united blow for our own freedom and that of the country generally. Once the majority agree to work Mr. Bevan's Bill the choice for the individual doctor will lie between submission or starvation, for no one seriously believes that a doctor outside the scheme will be able to make a living. Few patients will wish to pay private doctors' bills when they are already forced to pay for the State doctor. We have recently acquired a share in a practice after six years of separation

while one of us was in the Army, and we looked forward to taking our part in the State Medical Service. Economic security lies within the scheme. By refusing to join and finding ourselves in a minority we stand to lose a great deal; but so clear cut is the larger issue that we shall have to refuse to join the scheme as it now stands.—We are, etc.,

ZOE HARRIS.
PAUL HARRIS.

Langport.

The Epileptic at Risk

SIR,—On Jan. 18, 1946, I examined at the request of Dr. Sheppard, of Bridgwater, a woman aged 35 with a history of major epileptic attacks 15 years. I considered the diagnosis was unquestioned, and that there was considerable hysterical overlay. Electroencephalography showed an extremely wide spread of energy with activity in low, medium, and high bands, while frequency analysis showed that the general distribution of energy resembled that of the "spike and wave" spectrum of petit mal. It was considered that this electroencephalogram was strongly suggestive of epilepsy, with a liability for the patient to have both major and minor seizures. On my recommendation the patient received "epanutin" (sodium diphenylhydantoinate) 0.1 gm. t.d.s. with "luminal" (phenobarbitone) gr. 1/2 in the morning and gr. 1 at night. This therapy was instituted from the beginning of February. Three months later the patient's condition was reported considerably improved, with very marked reduction of fits and a general improvement in emotional attitude. On July '28 the patient and her mother went down to Devonshire on holiday. There they made contact with a Christian Science practitioner who apparently undertook treatment of this case. While in the house of the practitioner on Aug. 5 a local medical practitioner saw the patient and ordered her immediate removal to the North Devon Infirmary. She was admitted forthwith, and died the same day. At the inquest, as reported in a North Devon paper, the jury found "that death was due to exhaustion following epilepsy accelerated by the deceased being removed from constant qualified medical treatment." The coroner: "That means a verdict without culpability in the legal sense."

When it is considered advisable to put a patient on such a régime as I have detailed above every care is taken that patient, responsible relative, and general practitioner in charge are informed of the hazards involved in a discontinuance of "epanutin" without adequate premedication with phenobarbitone. I feel, Sir, that this admittedly unusual risk should be considered by our profession, though the application of a proper safeguard would seem to be difficult.—I am, etc.,

Taunton.

R. SESSIONS HODGE.

India's Problem

SIR,—I entirely agree with the opinion expressed by Sir John Megaw (June 29, p. 994) regarding the population of India. In my article on toxæmia of pregnancy read before the Scientific Section of the XVIII All India Medical Conference held Hyderabad (Deccan) in December, 1941, which was also published in the *Indian Medical Journal* dated May, 1942, I included as follows:

I fully realize that in our unfortunate and poverty-stricken country, where superstition and ignorance are rampant, and where children are born like rabbits, it is difficult to make our womenfolk go to the too few antenatal clinics in our country. If I had the power I would sterilize all men who have had more than three or four children, and have a clinic to teach contraceptive methods in all hospitals and dispensaries, and even induce abortion whenever anybody wants it.

As one who has practised midwifery for the last twenty-seven years I have come across hundreds of poor women of different communities who requested me to do something to stop their becoming pregnant any more. While the man only wants to satisfy his carnal pleasure it is the woman who feels miserable at her inability to feed, clothe, and educate her ever-increasing family—let alone the ruin of her health.

Is it any wonder that the average life of an Indian is only 27 years—the lowest in the world—that the average income per head is only Rs. 64. As. 6 per annum, and that a great majority are always submerged in debts?—I am, etc.,

Seppendurabai

T. D. RAO.

SIR,—I was glad to read the very courteous letter from Dr. Annie Megaw Brown (Aug. 24, p. 280). In particular I would like to congratulate her on the clarity with which she presents the two essential features of the situation in India: first the shortage of food in relation to the size of the population, and second the fact that what is needed in India at present is food rather than medicine in the majority of cases. The point of difference between Dr. Megaw Brown and myself is one of practical politics. There are many people in this country who have a slightly uneasy conscience in regard to India, but who are readily comforted by the dogmatic assertion that "Indians breed like rabbits," and that, therefore, there is no point in doing much about famine relief since it could merely encourage further rabbit-like behaviour. To focus attention on problems of population and birth control at a time when India is in the grip of famine is to encourage this inhuman attitude and so reduce support for the efforts of the India Relief Committee to place India's case for an increased allocation of food exports fairly before the food exporting countries. Surely it is obvious that of the two variables, food supply and population, the former can be altered more readily than the latter. The cases which Dr. Megaw Brown quotes are additional evidence, if any were needed, that India, though an ally, is faring much less well than our ex-enemies Germany and Japan. It is obvious that distribution of imported grain in a country such as India presents special economic and administrative problems. (If the average income is inadequate to purchase 10 oz. (300 g.) rice a day this would suggest that possibly the price level is fixed too high.) This is however no excuse for abandoning the effort to obtain supplies for India's starving millions until such time as that country is able to set her economy in order and utilize her vast natural resources, which when mobilized are more than adequate comfortably to support her present population.—I am, etc.,

Dumfries.

BRIAN H. KIRMAN.
Major, R.A.M.C.

Colonial Medical Service

SIR,—The letters appearing in your columns from various parts of the Empire portray the existence of some degree of general discontent at present conditions in the Colonial Medical Service. From my own experience and from discussion with members from different sections of the service I feel the discontent is justified. There is an acute shortage of staff, but this is not entirely due to the war. Many good men, some of them under fifty, have retired within the last twelve months, and it would not be far wrong to say that most of them did so for financial reasons and a sense of frustration due to stagnation in the senior ranks. It may be reasonable to assume that unless something is done to improve the terms of service it will become increasingly difficult to maintain the Service at strength. For very few men will commit themselves to almost lifelong existence in the tropics, with all that that means, including possible separation from wives and families, for a financial reward which, considering everything, compares unfavourably with that obtainable at home. A man with a D.P.H., for instance, may reasonably expect to be promoted to a senior post at home, such as that of county M.O.H., and receive a salary which may be considerably more than that of the director of medical services of a colony with 4,000,000 or more inhabitants. There are of course "superscale" posts in the Colonial Service, but these are not the prizes one might gather from advertisements. Most of them are worth only £1,200 or £1,300 per annum if one excludes directorships, which are few, which may take a quarter of a century to obtain, and are worth only £1,500 per annum in many of the larger colonies. A comparison with the recommendations in the Spens Report shows the total inadequacy of salaries in the Colonial Medical Service and the necessity for early improvement.

The Service is a good one from a professional point of view and provides wonderful opportunities for original work. Such work is not frowned upon, nor is an unduly large proportion of one's time devoted to paper work. One normally gets a fair deal locally and always from the Colonial Office. No service is perfect, and the Colonial Medical Service is no exception, but in spite of hard work, often in most unhealthy localities, I must frankly state that I have enjoyed my time as a member of it. But when I retire after more than twenty-five years

service I shall have to "look for a job," because a low salary and a low pension factor will give me a pension which will be insufficient for the proper maintenance of my family. That, surely, is wrong.

I would like to see the Colonial Medical Service, which has played such an outstanding part in the development of our Empire, improved and strengthened so as to make it attractive to the best in our profession. It would be a sad day if failure of recruitment were to make it necessary to staff this Service by "directed" (or "pressed") doctors from the U.K.—I am, etc.,

"AFRICA"

Population Statistics in Palestine

SIR,—I am grateful to Dr. I. S. Fox for his rather vitriolic reply (Aug. 17, p. 245) to my letter on Palestine—if only as an example (though sorry it should be afforded by a member of my profession) of the way in which prejudice can blind people to facts. Dr. Fox mentions many things which were present in the minds of most of us who were in the Palestine administration as factors which would eventually increase the power of that country to absorb a much greater population, but all these are long-term policies. The population pressure in Palestine after the 1914–18 war was immediate and urgent, but its needs could not be met until world conditions had improved. The unlearned Arab could not know this, nor could he realize that his own natural increase was a main factor in his increasing misery. What he did see was a lot of new people threatening to dislodge him, and he naturally jumped to the conclusion that they were the cause of his own food difficulties. It was this situation which we foresaw, which I tried to describe, and against which we tried to guard.

If Dr. Fox could get hold of the White Paper which gives Sir Herbert Samuel's report on the first Jaffa riots he would see that in it he confirms that it was the impossibility of the country to absorb so many new people—immigrant and home-born—that was the immediate cause of the riots; in other words, that the medical reading of the population statistics was correct. This fact makes hay of all Dr. Fox's arguments, which are unsound on the face of them, as they quite overlook the time factor which my letter emphasized. I hope that this time I have made myself clear. If Dr. Fox had been in Palestine at the time and seen, as I had, grain prices redouble themselves in a month I do not think that even he would have wished to admit more people; and he would have recognized that the advice given was, as I said, "in the interests of Jewish immigration," and not with any idea of obstructing the aims of the Government we were engaged to serve.

A common Arab proverb runs: "Haste is of the Devil." If the Zionists had given due heed to the customs of the East, as the pre-Zionist Palestinian Jews did, they might now be enjoying friendly relations with their neighbours.—I am, etc.,

Winsford,

W. N. LEAF

* This correspondence is now closed.—ED., B.M.J.

Prevention of Venereal Disease

SIR,—Let it be granted that it is a heresy "that to refrain from promiscuity is unnatural, abnormal, or even detrimental to health," yet Mr. W. Wagland (Aug. 31, p. 313), who asserts this proposition, has apparently failed to appreciate the point that Dr. G. G. Thyne was trying to make. Unfortunately the latter overstated his case by making the exaggerated statement, "It would be a very strange man, whether he was a venerable dean or a bus conductor, who has not at some time or other run the risk of venereal infection." If he had contented himself with saying "many a man, whether venerable dean or bus conductor, has at some time or other run the risk of venereal infection" few would have cavilled. To say, however, that it is "strange" not to run such a risk argues a very limited experience of men and women and opens the way for such replies as that of Mr. Wagland, who regards such an assertion as being an insult to a large body of men and women who deliberately choose continence until they are married.

The purpose of Dr. Thyne's letter was to advocate compulsory treatment for venereal disease. (It is to be noted that both

letters are headed "Notification of Venereal Disease," but in neither case is there any mention of notification.) Obviously the large body of men and women to which Mr. Wagland refers is of no importance in connexion with control and prevention of venereal disease, for by definition they do not run any risks. Obviously if the large body made 100% of the community the venereologist would no doubt be enjoying premature superannuation. Any large population group, however, consists of all sorts and conditions of men and women, some of whom do in fact run risks of acquiring venereal disease and many of whom may rationalize their promiscuity as being necessary for health. The fact that it is a heresy will not stop them, for they are driven by far more powerful urges than an enlightened appreciation of what is good for health.

When to promiscuity there is attached a very considerable degree of social irresponsibility it becomes arguable that compulsory treatment of venereal disease should be a matter of legislation. The experience of the health authorities in the Scandinavian countries is a strong point in favour of such legislation. It would be found as a matter of practice that in only a small proportion of cases of venereal disease would it be necessary to use compulsion, but it is in just that proportion that compulsion is the only remedy, since persuasion is of no avail. Liberty of the individual is a fine ideal, but that liberty should not imply the freedom to spread venereal disease and thus injure other members of the community.

Mr. Wagland's letter is a valuable contribution to the long-term policy of prevention of venereal disease, but absorption in such a policy must not be an argument for ignoring the fact that all men and women are not yet as Mr. Wagland would have them. We must not confuse what is with what ought to be. While the human animal in spite of all his achievements in some spheres remains on the whole a poor creature, it is but wisdom to say, "There, but for the grace of God, go all of us."—I am, etc.,

London, E.1.

F. R. CURTIS.

Protection Against Sexual Offences

SIR,—I am a little at loss how to answer Dr. Liebster's letter since it is difficult to believe that he is serious in his suggestion that every person convicted of a sexual offence against a woman or child should be castrated. He says that treatment should not be given because few patients appear to benefit from psychotherapy. He must be singularly unfortunate in his patients. Psychiatric clinics such as the Tavistock Clinic have published results which show that psychotherapy compares well with any other branch of medicine. Does Dr. Liebster suggest we should exterminate the tuberculous, for instance, because they are likely to infect others and are difficult to cure? With regard to castration I wonder if Dr. Liebster is familiar with studies of the Skoptzys and the eunuchs of the Chinese imperial palace. They often retained their sexual desires and capacities. Burton in his *Pilgrimage to Al Madinah and Meccah* mentions eunuchs who kept a number of wives. Castration was tried in Germany and America as a cure for sexual offences but seems to have been abandoned because it was ineffective. In any case to use it in such a wholesale way is using a steam hammer to crush a nut, besides being abominably cruel. Surely as physicians our aim is to try to cure and not to mutilate or punish.—I am, etc.,

London, W.1.

CLIFFORD ALLEN.

SIR,—Not so much as a prospective doctor (though I do happen to be a medical student) but as an ordinary citizen am I impelled to protest against Dr. L. B. Liebster's suggested penalty of obligatory castration for those convicted of sexual offences (Aug. 31, p. 313). How can a mutilating operation of this kind possibly be justified on social or ethical grounds? It carries to a monstrous extreme what is often called, far too euphemistically, "protective legislation." Underlying all such proposals one finds an over-simplified conviction that any means, however barbarous, justifies the dubious end of fool-proof social security. I submit that, while agreeing with those who regard the deterrent aspect of punishment as a legal and sociological necessity, we must draw a line—a pretty sharp, definite line, too—between what is ethically permissible and

socially convenient. This matter was well stated by an eminent jurist when discussing the problem of abolishing corporal punishment. Would it not, he remarked, be an admirable deterrent if we punished shoplifting by cutting off the offender's hands? On the same principle clearly Dr. Liebster would eliminate the organ which enables the offence to be committed. Does he not see the ultimate cruelty and absurdity of this philosophy?

My suggestion is that doctors should tread with care in matters concerning the reform of criminal law. They seem more often than not to display a crude ignorance of the juristic principles involved. If Dr. Liebster and others consider the penalties for sexual offences inadequate, are they possibly unaware that the convicted person can be sent to penal servitude for life? Furthermore, in respect of these people being found insane they can be safely lodged in Broadmoor. Anyway let us hope the law will think several times before it resorts to operative surgery in punishing criminals.—I am, etc.,

London, S.W.10.

J. A. FLETCHER.

SIR,—Dr. L. B. Liebster is pessimistic regarding the use of psychotherapy in the treatment of ungovernable erotomania leading to sexual assaults on women. And how should such pessimism be other than justified in a civilization which does not officially distinguish between self-control and control *ab extra*—indeed, which is constantly increasing the latter, and at great expense, in all walks of life? Assuming, then, further steady extension of the bureaucratic principle—i.e., the principle of forcing other people to be good—and assuming that young women are to continue going freely about the streets, not a few serious thinkers will be considering a possible need for the compulsory *veiling of women*, such as happened at the time of the rise of Islam. Indeed, so long as the leaders of civilization remain unaware of how to promote self-control in the individual the Moslem solution may prove the only alternative to wholesale compulsory sterilization of the male.—I am, etc.,

North Queensferry.

A. J. BROCK.

. This correspondence is now closed.—ED., B.M.J.

Pronunciation of Medical Words

SIR,—The derivation of our English words is always an interesting and instructive subject, especially to those who have had the advantage of having learnt something of Greek and Latin in their school days. I do not remember, though, that any of my schoolmasters ever troubled to give my classmates any instruction on this subject, which it seems to me now would have interested and afforded a pleasant quarter of an hour to his listeners. That no such instruction is given in our schools in these modern times would appear to be evident from one little incident which has given small jolts to my educational self-esteem during the past two or three years.

When doing assistantships in various parts of south-west England a case of gall-bladder trouble in my family caused me from time to time to visit chemists' shops to obtain cholelith pills. I have always pronounced the word "cholelith" with a hard ch, as in "choir" (Greek *χορός*) or "chronic" (Greek *χρονικός*) or even, to come more closely to the medical profession, as in the word "chemist," which is derived from the Greek word *χημία*, and which came to us through the French *chimiste*. Almost invariably my request for a bottle of cholelith pills has been met by the bright young person (generally female) behind the counter with the either pitying or contemptuous reply. "Oh! You mean chollylith pills," pronouncing the ch soft as in "chocolate," "choice," and "chuck." These rebukes or corrections from the chemists' assistants I always received with humility. It was wartime, so why be quarrelsome?

However, my latest experience has changed all that. The proprietor himself joined in and publicly rebuked me. This was too much! My pride was aroused. Had I not won a county council scholarship in my school days and graduated from a famous university in my adolescence? Am I not a member of a learned profession? Forthwith that evening I wrote to the firm which manufactures the pills and asked for a ruling on the matter.

The firm's reply was delicious and was balm to my soul. Whoever the gentleman is who was responsible for the reply he has a sense of humour as well as a considerable measure of fellow-feeling for me. He wrote:

"We would like to offer you our sympathy, in your verbal encounter with the 'bright young thing.' There is nothing more likely to arouse murderous thoughts in any man than to be corrected in his pronunciation. Moreover, in your own example, the exasperation will have been intensified by the fact that the rebuke was unjustified. Cholelith is pronounced ko-le-lith, and its derivation from the two Greek words *χολή*, meaning bile, and *λίθος*, a stone indicates that it should not logically be pronounced in any other way. We trust that this information will give you the pleasure of tactfully confounding the disdainful lady and thereafter extending to her the toleration of the wise for the ill-informed."

Just so! I'm waiting now for the member of my family to finish her present bottleful of 100 pills.

I thanked the company very warmly and requested permission to send the correspondence to the *British Medical Journal*. The company's reply caused me still more amusement and gratification.

"We think it is our place to thank you for a very pleasant interlude in the humdrum of general business. The touch of humour in your first note prompted us to reply in a similar spirit, feeling sure that we would not be held to be too frivolous. As for achieving immortality in the august columns of the *British Medical Journal*, this is quite beyond our reach. The Editor of that dignified periodical would shudder at the suggestion that he should sacrifice his space on so unprofessional a matter. For us it is enough to know that humanity and humour can still enter into business relations. Please accept our sincere thanks for that."

While I would regret any ill effects resulting from the shuddering, I do think that the above correspondence can be considered sufficiently professional to allow it to see the light of day. Certainly I think some of our friends in the chemical world may learn something from it.—I am, etc.,

Sussex.

CHARLES E. S. HARRIS.

. Another problem is the pronunciation of the Greek kappa. Most medical men, we believe, give it a hard sound in words like encephelitis and encephalopathy. Yet the Shorter Oxford Dictionary would have the sound soft.—ED. B.M.J.

On Reverence for Authority

SIR,—Your editorial note to the letter of W. G. Kierans (Sept. 7, p. 343) on Reverence for Authority prompts me to relate what Prof. Schäfer (this was long before he became known as Sir E. Sharpey-Schafer) said at a meeting, the first I think, of the Physiological Society at Edinburgh University. He had been speaking about the teachings of Galen and how because of Galen's authority his teachings had been accepted almost without question for some thirteen or fourteen centuries. He then went on to say that the erroneous statements of great men had often hindered the progress of knowledge more than the other parts of their work had favoured it. These are almost the exact words used by the professor, for with them in my mind I have often during the last thirty years wished I had had the literary ability to write a book on the ill-effects of the "erroneous statements of great men" in the various branches of science. A "Short History of Error" would be a fine companion volume to *A Short History of Biology* (Singer).—I am, etc.,

London, S.W.10.

G. POLLOCK.

Demobilized Service Medical Officers

SIR,—I would like to endorse most heartily Wing-Commander Stanley Turner's suggestion for a B.M.A. ex-Servicemen's Committee (Aug. 31, p. 312). Such a committee should have been in existence a long time ago and would have gone a long way towards making the ex-Service doctor feel that his case was well represented and put forward by people who understood his problem. I agree with the proposed constitution of the committee and would suggest that there should be six ex-Service members, two from each Service, and of these one to represent the specialists and the other the general practitioners.—I am, etc.,

ANDREW ZINOVIEFF,
Squad.-Ldr., R.A.F.V.R.

Obituary

On Aug. 26 Dr. THOMAS HOUGHTON MITCHELL died at his home in Ambleside, where he had practised for over half a century. Dr. Mitchell exemplified the best type of old-fashioned family doctor, beloved and trusted by very many as a faithful friend in the wide district in which he practised. He was born in Limerick in 1863, one of three brothers who all became doctors. He qualified as L.R.C.P. & S. Ed. in 1883 after completing his studies at Trinity College, Dublin, and took the M.D. degree at Durham in 1904. Entering Freemasonry in 1905 he gained many Masonic distinctions. Dr. G. Ainslie Johnston writes: After qualifying Dr. Mitchell spent two or three years holding hospital resident appointments at Inverness and Ayr and first came to Ambleside as locum tenent to the late Dr. H. Redmayne in 1887, when I had the pleasure of making his acquaintance, which led to a lifelong and very close friendship. Dr. Redmayne took him into partnership, and on Dr. Redmayne's retirement his brother-in-law, the late C. H. Hough, F.R.C.S., retiring from the senior surgeonship of the Derbyshire Royal Infirmary, became Dr. Mitchell's partner. Dr. Mitchell had a great sense of humour and was very widely read; he wrote a little and published "*Ars mendendi of Shakespeare*," and engaged in his younger days in lawn tennis, golf, and bridge (especially the two latter) in his, often scanty, leisure time. He had a very wide circle of friends among the residents and the visitors who come to our Lake District, who will long remember him. He married in 1893 Miss Gertrude Pease of Darlington, who died in 1935, and lost his only son on active duty with the R.A.F. at the end of the first world war. He is survived by three daughters, one of whom, Mairin Mitchell, F.R.G.S., is a well-known writer on maritime subjects.

Dr. JOHN BARBOUR STEWART, consulting surgeon to the Glasgow Eye Infirmary, who died last month, was a member of the B.M.A. for nearly forty years until his retirement on grounds of ill-health at the end of 1944. He was born in Glasgow, son of John Stewart, and from Garnethill School entered the University of Glasgow, graduating M.B., Ch.B. in 1902. His early appointments were those of senior resident surgeon at the Glasgow Royal Infirmary and at the Eye Infirmary. During the war of 1914-18 he paid regular visits to the Gartshore Red Cross Auxiliary Hospital to attend eye cases. He had also been visiting ophthalmic surgeon to Belford Hospital, Fort William. Dr. Stewart was a member of the Ophthalmological Society of the United Kingdom and of the Glasgow Royal Philosophical Society.

Miss HELENA GERTRUDE JONES, M.B.Lond., D.P.H.Camb., died on Sept. 4 at Gilnockie, Treorchy. She was born in 1870 at Llanrwst, N. Wales, and studied at the Royal Free Hospital. She was one of the original Fabians in the days of Shaw and Wells and became one of the leading suffragettes. Mrs. Pankhurst regarded her as her best orator, and when any trouble was expected she was always sent to quell the disturbance. After four years as resident in Woolwich Infirmary she went to Yorkshire as school medical officer. She worked in Corsica during the first world war for the Serbian Relief Fund. In 1916 she came to the Rhondda, where she was assistant to the M.O.H. and was in charge of the maternity and child welfare clinic. She did excellent work and was regarded as one of the best authorities on child welfare. Always of a forceful nature, thoroughly honest and forthright, she did invaluable work in the disturbed Valley until her retirement in 1935. At the outbreak of war in 1939 she immediately offered her service to Dr. Fergus Armstrong at Treorchy, and worked with him until her death. In the "blitz" of 1941 she was the first doctor on the scene and worked incessantly for twenty-four hours. A nurse who accompanied her was killed with twenty-three people in one street, but although over 70 years of age she carried on her work nobly. Her memory will be cherished for all time in the Rhondda Valley.

With the death of Dr. A. C. TURNER on Sept. 5 the City of Leicester, and more particularly its school medical service, has sustained an exceedingly great loss. Though he had no children of his own, Dr. Turner devoted his life in the truest sense to the care of children. Innumerable children and their parents both in Leicester and in Rotherham, where he served for many years, owe him the deepest gratitude for his kindly and efficient ministrations. His connexion with the Leicester School Medical Service goes back as far as 1911, when he was appointed the first assistant school medical officer. There are many references

in the annual reports of those far-off pioneer days to the value of his services. On the outbreak of war in 1914, Dr. Turner immediately joined the North Midland Field Ambulance and served throughout in France with great distinction, was wounded in action, was twice mentioned in dispatches, and was awarded the D.S.O. in recognition of his gallant service. It is characteristic of the man's humility that he kept the news of this distinction very much in the background. In 1922 he went to Rotherham as school medical officer, and remained there until 1935, when he returned to Leicester in charge of the school medical service there under the general direction of the medical officer of health. During the second world war he was the planner of the city casualty service, and his thoroughness, precision, and meticulous attention to detail made a most valuable contribution to the efficiency of the service. His selfless devotion to duty was most remarkable. During the last few months at his desk, in spite of increasing ill-health, he undertook the writing of a review of the service with which he was connected for so many years. His record of the Leicester School Medical Service from 1905-45 will long remain a classic example of what such reports should be. Such is a very inadequate review of his official life, but he was much more than an official. He gave an outstanding example of unselfish public service in war as in peace. He was a most reticent man, particularly with regard to his achievements, many and great though these were. He had a most lovable disposition, and his unexcelled stoicism during his long and final illness, so full of severe discomfort, was typical of his dogged determination to see all things through without a flinch. He met death as he met life, with a smile on his lips and calm confidence in his heart.

E. K. M.

Dr. EVELYN MARY HOWIE died at Newcastle-on-Tyne on Sept. 7. She was the first woman to receive her medical training at Newcastle-on-Tyne, and she qualified with the M.B.B.S. Durham, in 1902. The first ten years of her post-graduate life were happily and busily filled as a general practitioner's wife in Glasgow. Not only was she occupied with her three children, and all the duties that fall to a G.P.'s wife, but she greatly assisted her husband in his medical work, and there developed her lifelong interest in the care of young children. She was widowed in 1912, and then began the hard part of her life. Hers was only a frail constitution, and she was left no better provided for than is the average doctor's widow. Yet she succeeded conspicuously in both her private and medical life. She was able to maintain a home for her children and to give them a first-class school and professional education, so that now one is a doctor, another a solicitor, and the third a chartered accountant. In her professional life she was engaged in maternity and child welfare, and in 1920 was appointed maternity and child welfare medical officer to Durham County, a post which she held for 17 years until her retirement in 1937. These were the formative years of child welfare, and much that is now standard practice all over the country was influenced by her work. In 1928 she was elected to the Council of the Medical Women's Federation. No doubt the hardships of her own life gave her an added insight into the problems of a working-class mother's life, which earned for her so much affection from the people for whom she worked.

By the death of HAMILTON G. LANGWILL, Leith and the surrounding district has lost a much respected and highly efficient general practitioner, who had been in practice for the last 45 years. He graduated M.B., C.M. in 1889, M.D. in 1893, and received the diploma of F.R.C.P. Ed. in 1896. After graduation, he served as house-physician in the Simpson Memorial Hospital, and in the Sick Children's Hospital, Edinburgh. After that experience he started work in Leith and was appointed physician to Leith Hospital. During the 1914-18 war he served as captain, R.A.M.C., in the 2nd Scottish General Hospital. He was also lecturer at Leith Nautical College. J. J. W. writes: He and I graduated in the same year, and kept up our friendship and association to the end of his life. He was a most energetic and likable man, kind and thoughtful, and never spared himself in assisting his friends and patients in their troubles. In addition to his professional work he had many interests, as he was well informed in general literature, and was a deep admirer of the works of Robert Louis Stevenson. His musical knowledge was very wide, and he was a regular attendant at all the most important concerts in Edinburgh and enabled many of his friends to share his pleasure by giving them tickets of admission. Perhaps his most outstanding interest was his knowledge of the beauties of churches and cathedrals of Scotland and England which he visited during his holidays, and from which he came home with numerous photographs and apt

descriptions of all that he had seen. I know he will be much missed by all his patients and personal friends in Leith and Edinburgh, but especially by his married daughter. Fortunately he had a very short illness, and worked practically to the last, which I know he would have wished.

We regret to announce the death on Sept. 8 at Crowborough of Lieut.-Col. ASHTON STREET, I.M.S. (ret.), who was for a succession of years a popular member of the Dominions Committee of the B.M.A. and of the Central Council. Born in 1864, he began the study of medicine at Downing College, Cambridge, and afterwards took his clinical course at Leeds. He qualified as M.R.C.S. in 1885 and four years later obtained the M.B. degree at Cambridge and the F.R.C.S. diploma. His first appointment before joining the I.M.S. was that of house surgeon at the Leeds General Infirmary. During his service in India he was surgeon to and professor of anatomy at the J.J. Hospital, Bombay, and later principal and professor of surgery at the Grant Medical College. Col. Street was elected to the Council of the B.M.A. in 1927 and on three occasions acted as a representative at Annual Meetings. He married the daughter of Herbert Davies, M.D., senior physician to the London Hospital, and leaves two daughters.

A. TUDOR EDWARDS, F.R.C.S.

At a memorial service held in London on Sept. 12, Lord HORDER gave the following address:

With spirits still benumbed by sorrow it is not easy to speak about one who, until two weeks ago, was so much with us as was Arthur Tudor Edwards. Certainly to speak perfunctorily of anyone so vital as he was is not possible. It is only when we broaden the theme and deepen its perspective that we can say anything that begins to express what is in all our minds. And so, in speaking of Tudor Edwards to-day, if I speak for Medicine my task becomes simpler, and at the same time my approach to it becomes more fitting.

In addresses like this of mine a distinction is often made between the man and his work. In the case of our friend and colleague the distinction is even less justified than with many other men. For to a very notable degree the man was his work and the work was the man. As we watched his whole personality infuse itself into his pioneering labours the single heart held us all to ransom. This terrific concentration of the spirit was the impelling force which enabled Tudor Edwards to break down the barriers that tradition had set against the entry of the surgeon into the as yet unexplored field of chest diseases. He made the entry; he followed it by a series of triumphant achievements; and he proved convincingly that others could do as he had done. But they must show the same courage, the same care and—as many of his pupils must have thought it—the same painful thoroughness. Such care, such thoroughness left in the case of Tudor Edwards no time nor place—as there was indeed no inclination—for showmanship. And yet the whole world was watching, was repeating, was testing his results, to find them valid and of tremendous service to humanity.

Recognition of Tudor Edwards' work was to be in terms of quality, not quantity. International leaders in his field of action realized that they had a peer, and this was the kind of distinction he liked best. Invitations to go here and to go there were honourable but they were embarrassing. The claims of Brompton, The London, Midhurst, Millbank, and Roehampton, doubled as they were by the war casualties, remained paramount. These were the places to which Tudor Edwards was adding fresh lustre. And to these many obligations he added those entailed by being adviser to the Ministry of Health, consultant to the R.A.F., and a member of the Council of the Royal College of Surgeons.

Seven years ago came the first warning that the physical and mental strain, if pursued, might exact the fullest payment. So great was the impelling force of the man's technical genius that, were it not for the agonizing fear of separation from his beloved helpmate, I do not think a choice really existed for him. There was certainly no drama: posturing had no attraction for Tudor Edwards. The situation was dominated by the lure of scientific and beneficent achievement. Let us not ignore the lesson. This man was absorbed in the single-hearted, single-minded mastery of his craft. All else was secondary. Let us never forget and never lightly sacrifice this essential ingredient in the character of the true healer. Society, in its best interest, must harness all that it can summon of this force to the plough of medicine. To bring Nature under control in respect of her hidden secrets is the way the pioneer serves his fellows. To-day it is the conquest of the microbe; to-morrow it is the successful pitting of the surgeon's craft against the cunning concealment of vital organs. It was to this battle that Tudor Edwards gave his life. He will remain for all who knew him a profoundly satisfactory personality and a surgeon of flawless tech-

nique. Commentators say that Tudor Edwards was handsome. Ho true, but the word is inadequate if we apply it only to his bodily features. He was beautiful in the work of his hands and he was handsome in his mind. In his being there was no meagre expression of compensation. It was as though Nature said at his birth: "what I can do when I have no inhibitions and hold back no reserve." Tudor Edwards died in his prime, without a grey hair on his head or in his mind. He has left two precious legacies: to those who knew him a joyous memory; to the world a new chapter in the liberation of mankind from pain and suffering.

Universities and Colleges

UNIVERSITY OF GLASGOW

Dr. Thomas Anderson, F.R.C.P.Ed., physician-superintendent of the Knightswood Hospital, has been appointed full-time lecturer in infectious diseases in the University of Glasgow from Oct. 1. During the past year a joint committee formed by the University and the Corporation of Glasgow has been discussing such a project. It was felt that as the Public Health Department of the Corporation was responsible for the care of patients with infectious disease and the University was anxious to ensure the adequate teaching of this subject, joint responsibility was desirable. The new appointment is a University one, however, and the lectureship is independent of the Corporation. The belief behind the conception is that there is an increasing need for continued study of the management and prevention of infectious diseases. The preoccupation of those in charge of fever hospitals with the day-to-day administration thereof tends to make a serious demand upon their time as clinicians. The new position will free Dr. Anderson from this side of the work and allow him to devote his full time to the clinical aspects of the subject. In order that he may have adequate clinical material for teaching and for investigation the appointment carries with it the title of visiting physician to Knightswood Hospital, and he will have full clinical responsibility for the treatment of the patients there; he will in addition be consultant in infectious diseases Glasgow Corporation. Dr. Anderson's successor as superintendent of the hospital is to be appointed.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a special meeting of the Council on Sept. 27 the Honorary Fellowship of the College will be conferred on Mr. Victor Bonn in recognition of his eminent services to British gynaecology.

The Services

Surg. Rear-Admiral C. E. Græson, C.B., has been appointed an Honorary Physician to the King in succession to Surg. Rear-Admiral F. J. D. Twigg, C.B.E., who has been placed on the Retired List.

The following appointments and mentions in dispatches have been announced in recognition of gallant and distinguished services while prisoners of war:

M.B.E. (Military Division).—Major (acting) T. M. Pemberton and Capt. W. H. McDonald, R.A.M.C.

Mentioned in Dispatches.—Lieut.-Col. St. C. E. J. Barrett, Lieut.-Col. (Temp.) H. C. Benson, W. G. Harvey, E. M. Hennessy, O.B.E., J. Huston, J. W. Malhol, O.B.E., M.C., and J. H. Strahan; Major E. A. Smyth; Majors (Temp.) F. E. Anderson, V. Bennett, and W. J. E. Phillips; Majors (Acting) R. C. Burgess and F. L. Webster; Capt. F. E. Butterfield, P. T. Chopping, D. Christison, M. H. Churchill, T. R. S. Cormack, E. K. Cruickshank, F. L. K. Daniels, J. D. Gibb, J. R. Gibbs, C. Hecht, J. K. Hewat, B. Lennox, C. V. Lewis, P. McArthur, J. McQuillan, E. R. S. Phillips, and C. S. Pitt, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Killed in accident to air-ambulance.—Surg.-Cmdr. William Tudor Gwynne-Jones, R.N.

The *Annals of Tropical Medicine and Parasitology*, 1945, 39, Nos. 3 and 4, a special number issued as a memorial to Prof. Warrington Yorke, F.R.S., is now available in the B.M.A. Library. It contains a series of papers describing the investigations into certain new antimalarial drugs culminating in the discovery of paludrine. (An article entitled "Paludrine in the Treatment of Malaria," by B. G. Macgrath and colleagues in the Liverpool School of Tropical Medicine, appeared in the *Journal* of June 15, 1946, p. 903.)

No. 35

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 31.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary cases for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In England and Wales 79 more cases of scarlet fever were notified. Apart from the administrative areas of Southampton and Durham (each with 10 fewer cases) the increased incidence was fairly evenly distributed throughout the country.

Measles, whooping-cough, and diphtheria were responsible for 575, 82, and 23 fewer cases respectively. The decline in typhoid cases was maintained for the third week in succession, 27 cases (9 less than last week) being reported. A decrease of 22 cases of paratyphoid also occurred, the total falling to 44.

The decline in measles was consistent in the northern counties, but small increases were noted in a few midland and southern areas. The greatest decrease, of 87 cases, occurred in Essex. Whooping-cough notifications varied considerably from the regional aspect, for, although decreases of 46, 30, and 26 were reported from London, Sussex, and Kent respectively, increases of 70 occurred in Lancashire and 33 in Derbyshire.

In Scotland 81 cases of paratyphoid B were reported. This represented an increase of 74, of which as many as 65 were due to increased notifications from Coatbridge in Lanarkshire. Four new cases also occurred in Renfrewshire and 3 in Airdrie. In addition to 3 cases of paratyphoid at Glasgow (one more than last week) 2 of the 3 new typhoid cases notified for Scotland occurred in that borough. Whooping-cough, diphtheria, measles, and scarlet fever were responsible for 50, 15, 13, and 8 more notifications.

In Eire diarrhoea and enteritis again showed an increased incidence, 65 cases being reported—an increase of 41—of which 55 cases were notified for Dublin, compared with the previous week's figure of 19. Increases were also evident in the notifications of whooping-cough, scarlet fever, and measles, but there were no fresh cases of typhoid.

Quarterly Returns for Scotland

During the quarter ending June, 1946, the births were equivalent to a rate of 20.2 per 1,000, being 1.3 greater than the average rate for the corresponding quarter in the preceding five years. (The average, so calculated, is used as a standard of comparison throughout this note.) Infant mortality, with a rate of 47 per 1,000 live births, was 17 below the average. The deaths from all causes were equivalent to a rate of 12.2 per 1,000 population—1.4 less than the average.

Respiratory tuberculosis caused a death rate of 64 per 100,000, and all forms of this disease resulted in a rate of 82 per 100,000 (the average figures were 63 and 87 respectively). Actual deaths from the main epidemic diseases were: cerebrospinal fever 26, whooping-cough 19, diphtheria 16, and measles 39.

Week Ending September 7

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 663, whooping-cough 1,824, diphtheria 284, measles 1,321, acute pneumonia 292, cerebrospinal fever 33, dysentery 86, acute poliomyelitis 19, paratyphoid 42, and typhoid 21.

Medical News

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel (Embankment entrance) on Friday, Oct. 4, at 7 for 7.30 p.m.

The St. Thomas' Hospital old students' dinner will take place at Claridge's Hotel, Brook Street, W., on Nov. 1, at 6.45 p.m. for 7.30 p.m., with Sir Maurice Cassidy, K.C.V.O., M.D., in the chair. Rationing restrictions limit the number of places to 250. Applications from old St. Thomas' students should be made to the honorary secretaries, Old Students' Dinner, St. Thomas' Hospital, London, S.E.1.

The next meeting of the Whips Cross Hospital Medical Society will be held on Thursday, Oct. 3, when Dr. John Shone of the North London Blood Supply Depot will lecture on blood transfusion and the general practitioner. The honorary secretary of the society is Dr. W. W. Walker, Whips Cross Hospital, London, E.11.

The 22nd meeting of the Biochemical Society will be held in the Department of Biochemistry, the University, Liverpool, on Friday, Sept. 27, at 11 a.m., when papers will be read.

At the Welsh National School of Medicine, Cardiff, the opening address for the new session will be given by Sir Willem Jameson, Chief Medical Officer to the Ministry of Health, in the Institute of Physiology, Newport Road, Cardiff, on Friday, Oct. 4.

The International Society of Medical Hydrology will hold its first post-war meeting at Buxton on Friday, Saturday, and Sunday, Oct. 4, 5, and 6. The train leaves St. Pancras at 11 a.m. on Friday, and there is a general meeting of members at 5 p.m. On Saturday at 9 a.m. Dr. Van Breemen will read a paper on the four causal factors of rheumatic disease in connexion with medical hydrology, followed by a demonstration of cases at the Royal Devonshire Hospital, and a visit to the spa; at 5.30 p.m. Mr. R. Whittington will read a paper on plasma viscosity. The programme for Sunday, beginning at 9.30 a.m., includes papers by Dr. Victor Ott on present Swiss concepts of rheumatism and physical medicine, by Dr. Abraham Cohen on the use of physostigmine in rheumatoid arthritis, and by Dr. Louis T. Swaim on American concepts on arthritis. Applications for attendance and for accommodation should be made to Dr. Donald Wilson, 28, The Circus, Bath. The fee for non-members at the meeting is 10s., exclusive of accommodation.

A conference of the Nutrition Society is being held to-day (Saturday, Sept. 21); beginning at 10.30 a.m., at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C. This precedes a general business meeting at 2.30 p.m. The provisional programme and time-table are as follows: "The work and aims of the Food and Agriculture Organization." Papers by Sir John Orr, Director-General of F.A.O.; Mr. D. Lubbock "Nutritional Aspects of the World Food Picture"; Dr. P. Lamartine Yates "The Development of Food Supplies"; Dr. W. R. Aykroyd "The Nutritional Programme of F.A.O."; Miss E. Fauz "World Needs for Processed Milk." Non-members are only admitted to meetings by the introduction of a member. Further details of the Nutrition Society can be had from the hon. secretary, Dr. Leslie J. Harris, Nutritional Laboratory, Milton Road, Cambridge.

The Royal Photographic Society's 91st annual exhibition of photography was opened by Sir Henry Dale on Sept. 14, and will be on view from 3 to 6 p.m. until Saturday, Oct. 26, at the Science Museum, Exhibition Road, London, S.W. It contains nearly 900 photographs, and entries were received from 21 countries. There are prints showing the photographic method in nuclear research. Other prints illustrate such diverse subjects as sound recording on glass disks, the effect of electron bombardment, the formation of shell on an egg inside the hen shown by radiography, the making of a denture, diseases of plants, photographs of molecules (taken by the x-ray diffraction method of Sir Lawrence Bragg), a paraffin spray taken at 1/10,000 second, antenatal skiagram of Siamese twins, colour photographs and transparencies of medical and surgical subjects, and many beautiful natural history prints. The cinematographic section contains 46 films on scientific, technical, commercial, and instructional subjects.

The Board of Directors of the famous Scottish institution known as Crichton Royal have established three Fellowships for the training of specialists in psychiatry, each carrying a salary of £400 a year, plus the usual residential emoluments. The Fellowships are in addition to the ordinary staff of the hospital; they will be tenable for one year, starting from Feb. 1 next, but may be prolonged for another year. Previous general hospital experience is essential. The Fellows will receive training in all branches of clinical psychiatry (including work in out-patients and child guidance clinics) by the senior members of the medical staff. These Fellowships will help the introduction of a higher and fuller training in psychiatry as encouraged in the recommendation of the Royal College of Physicians. Application forms and syllabus can be had from the Physician-Superintendent, Crichton Royal, Dumfries, and should be returned by Dec. 16.

Thirty members of the medical delegation from Belgian universities now visiting this country were welcomed in London on Sept. 9 by Sir Ronald Adam, chairman of the British Council. The reception was held at 74, Brook Street, and among those who met the medical representatives from Brussels, Ghent, Liège, and Louvain were the Belgian Ambassador, Lord Moran, P.R.C.P., Sir Gordon Gordon-Taylor, and Lord Amulree, representing the Ministry of Health. The delegation was led by Prof. J. J. P. Bouckaert of Ghent, deputizing for Prof. J. P. Hoet of Louvain.

The National Ophthalmic Treatment Board announces that Dr. Alfred Cox is resigning his position as Acting Secretary of the Board as from Sept. 30, and that Miss M. H. Atkins has been appointed Secretary to the Board. Dr. Charles Hill will continue as Medical Secretary, the post formerly held by the late Dr. G. C. Anderson.

Dr. G. Candler-Hope, who has been medical officer of health for the Scarborough Rural District for 51 years, is retiring at the end of this month. Dr. Candler-Hope graduated in medicine at Edinburgh in 1891 and joined the B.M.A. in 1900. He served as a member of the Representative Body for 20 years in all between 1920 and 1943; he was also a member of the Distribution Committee and of the Rural Practitioners Subcommittee for a long period.

Letters, Notes, and Answers

All communications with regard to editorial business should be addressed to the EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: WESTCENT, LONDON. ORIGINAL ARTICLES AND LETTERS for publication are understood to be offered to the *British Medical Journal* unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt. Authors over-seas should indicate on MSS. if reprints are required, are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: Articulate, Westcent, L. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY, Association. TELEPHONE: EUSTON 2111. TELEGRAMS: Mediscera, London.

B.M.A.-SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

ANY QUESTIONS?

Blood Sedimentation Rate

Q.—Can an active tuberculous or rheumatic infection in a patient whose sedimentation rate is normal for age and does the amount of sodium salicylate in the blood affect sedimentation rate? Is there any value in taking reading both one and two hours (Westergren)?

A.—It is impossible to deal with this question completely in a brief answer. A useful symposium of several authoritative articles on various aspects of the blood sedimentation rate will be found in *The Practitioner* (July, 1946). These articles include useful bibliographies.

While in the active phases of tuberculosis and acute rheumatism the sedimentation rate is usually increased and the degree of this increase is roughly parallel to the activity of the disease. Cases are occasionally met in both these infections in which the sedimentation rate is within normal limits. This is especially true of tuberculous lesions of minimal extent, where it has been shown that the sedimentation rate when patients first come under observation is quite unreliable as a guide to the probable course of the disease. In tuberculosis and rheumatism the sedimentation test finds its greatest value in serial observations, when variations in rate in the same subject are of undoubted significance and form a useful addition to other data in assessing progress. Definite information is available about the effect of sodium salicylate on the sedimentation rate, but it seems likely that if there were any such effect it would have come to light, since the test has been used extensively in cases of acute rheumatism in which salicylates are often given over long periods.

With regard to the value of observations after one and two hours by the Westergren method, for clinical purposes a reading at one hour is adequate, and little further information of value is likely to be obtained from reading after two hours. Sedimentation of red cells occurs in three phases: an initial phase in which the red cells are agglutinating and in which the rate of sedimentation is gradually increasing; then a phase of sedimentation at a fairly constant rate after the process of agglutination is completed; and finally a phase of gradual slower sedimentation as the red cells pack at the bottom of the tube. In the Westergren method, with its 200-mm. tube-length, the reading at one hour will include the first phase, but in the case of the most rapidly sedimenting bloods the whole of the first hour will fall into the phase of constant sedimentation. The second hour will include a variable proportion of the phase during which sedimentation is slowing because of packing of red cells. Methods using a 100-mm. tube and a reading at one hour will lead to the inclusion within the time covered by the reading not only of the whole of the first phase but also of part of the third phase with rapidly sedimenting bloods. Various methods have been devised to measure the steady sedimentation rate during the second phase which on theoretical grounds would present several advantages, but for clinical purposes the test cannot be interpreted with sufficient accuracy to justify the added complication introduced by these methods.

The test is not specific; the rate of sedimentation depends not only upon the balance of the protein and certain other

constituents of the blood but also upon the concentration and shape of the red cells, and the first of these can be disturbed by a great variety of factors. In view of the non-specificity of the test it seems preferable for the clinician to allow for any anaemia that may be present in his interpretation of its result in relation to the total clinical picture, rather than to attempt to remove the effect of one among many variables by a correction for anaemia. Hence a simple reading after one hour with the Westergren technique conveys sufficient information for all except special investigational purposes.

Treatment of Chronic Sinusitis

Q.—A woman aged 48 had her antrum of Highmore drained for double sinusitis fifteen years ago. The right antrum frequently becomes inflamed, causing intense pain which is only relieved after a profuse muco-purulent discharge from the right nostril. These acute attacks have recurred every few weeks for several years. *Staph. aureus* is the chief organism present. Surgical measures are declined. Is penicillin indicated?

A.—It is unlikely that penicillin would cure this patient even if the organism were sensitive to penicillin, as the infection is chronic, with formation of fibrous tissue and osteitis, where the penicillin would not penetrate. Proper drainage and removal of infected bone in the capsule of the sinus is indicated.

Intestinal Worms Stained with Iron

Q.—An infant under treatment with iron ammonium citrate passed black thread-worms. It was presumed that the worms were made black by feeding on the iron. Was this observation true?

A.—The cuticle of living helminths, in contrast to that of dead helminths, usually resists staining by substances other than vital stains. The blackening of the faeces in persons taking iron ammonium citrate is presumably due to the formation of ferrous sulphide, which, if taken into the gut of the living worm, would be visible through the transparent cuticle.

D.D.T. for Head Lice

Q.—Is D.D.T. efficacious and safe to use on a verminous head? How should it be applied?

A.—D.D.T. can be used in the form of a 2% emulsion against head lice. (See the article by E. B. S. Scobbie in *British Medical Journal*, 1945, 1, 409.) It is fairly certain that one or two such treatments would be harmless, but the effects of repeated applications are not known. We understand that experiments are now in progress to ascertain the effectiveness of D.D.T. aqueous suspensions for this purpose. Such preparations would clearly be safer than emulsions owing to the absence of any solvent for the D.D.T.

Effects of Penicillin Lozenges

Q.—Penicillin lozenges are in common use, yet the American "Digest of Treatment" states that 18% of cases using them develop glossitis and stomatitis. Their use for infections of the oral cavity is considered inadvisable. What is your opinion?

A.—It is impossible to trace the American *Digest of Treatment* anywhere here. It cannot therefore be discovered on what kind of information the statement is based that 18% of cases using penicillin lozenges for the treatment of infections of the oral cavity develop glossitis and stomatitis.

It is impossible to obtain exact figures for the use of penicillin lozenges in oral infections in this country, but many cases have been treated in this manner, and only four cases of glossitis have so far been reported—two by P. D. Bedford, *British Medical Journal*, 1946, 2, 63, and one by P. Ellinger and F. M. Shattock, *British Medical Journal*, 1946, 2, 208. This demonstrates that the incidence of glossitis following oral penicillin treatment is very rare. There is no permanent damage to the tongue, and the glossitis disappears after discontinuing the treatment. In the one case investigated more thoroughly a nicotinamide deficiency was observed which was probably due to an effect of penicillin on the production of nicotinamide by the intestinal flora. It was the main cause of the glossitis, which could be relieved by

parenteral administration of nicotinamide. Considering the great therapeutic value of local penicillin treatment of oral infections, and the very rare incidence and the complete and speedy reversibility of the glossitis, unpleasant as it might be for the few people who acquire it, there is no indication against the use of penicillin for the treatment of oral infections. One should, however, watch the condition of the tongue and look for other signs of nicotinamide deficiency during treatment, which should be discontinued and nicotinamide given parenterally if such signs develop.

Erythematous Patches on Legs

Q.—A woman aged 39 complained in 1941 of pain in the right groin; temperature 103° F. (39.4° C.). Nothing could be found on examination. Her temperature fell on the second day, and there appeared on the right leg a large erythematous patch which took 1-2 weeks to disappear, leaving a large area of scaling. This type of attack has occurred five times—four on right leg, one on left. Between the attacks she is well. I should have diagnosed erythema nodosum but for the recurrences. What is your opinion?

A.—Erythema nodosum is often recurrent, but the history does not suggest that diagnosis. The condition is almost invariably bilateral, and is not preceded by glandular symptoms or temperature (though temperature often accompanies the onset). The colours characteristic of erythema nodosum are not described and the scaling does not seem compatible with that diagnosis.

The probable diagnosis is a recurrent phlebitis or recurrent lymphangitis, organisms possibly gaining entrance through some minute abrasion about or between the toes. It is important to exclude ringworm infection between the toes. Treatment should be according to the findings.

Intestinal Enzymes for Arthritis

Q.—It is suggested that enteric-coated capsules of crepsin-type enzymes may have a beneficial effect on rheumatoid and other types of arthritis. Has this treatment any rationale?

A.—Claims made by the originator of the treatment of rheumatic diseases by a preparation of intestinal enzymes have not been confirmed by others. The writer believes that the remedy has some influence upon digestion and assimilation; and he has noted an improvement in general health and therefore improved powers of resistance in some of the patients, while in others no effect could be observed. That the remedy is by no means inactive is shown by the marked fall in the blood sugar which sometimes occurs under the treatment as well as other less obvious effects, and this would indicate the desirability of further observations. It may throw some light on many little-understood features in the pathology of rheumatoid arthritis in particular.

Stammering in a Young Child

Q.—A child aged 2 years 9 months is beginning to talk and shows signs of a stammer. Can you tell me what treatment is indicated, if any?

A.—At this stage it is not uncommon for an intelligent child to develop a temporary stammer because his flow of ideas is outrunning his verbal facility. In such a case one can safely ignore the symptom so far as direct treatment is concerned, but it is useful to adopt certain measures to decrease its duration and to prevent habit formation. These include speaking to the child slowly and distinctly, with economy of words and simplicity of phrasing, since the stammer may well be an unsuccessful attempt to imitate the rapid and complicated speech of adults too early. It is also advisable to provide plenty of other means of expression, especially in play, with simple construction material and the large toys that give a satisfying sense of power to small children. Songs are sometimes a help in combining words with rhythm.

A developmental stammer is usually of the repetitive kind, without any marked hold-up in breathing. The type that involves spasmodic working of the throat muscles followed by explosive speech should, if at all persistent, be referred to a speech therapist, as should cases with a family history of marked stammering.

INCOME TAX

Child Allowance

W. O.'s son, aged 21 years, is taking a degree course at a university. He receives a Government grant conditional on W. O. contributing £10 a month towards his maintenance. Can W. O. claim the child allowance?

** Yes.

New Partnership

"ALPHA" has acquired a share in a partnership as from April 1, 1946, but the outgoing partner retains certain appointments to the value of £300 per annum. A new bank account has been opened as from April 1. Alpha did not buy a share in the previous book debts. How should his liability for the year to April 5, 1947, be calculated? He also asks whether purchase tax is deductible for income tax purposes.

** It is assumed that the new firm will be regarded as a continuation of the old one, and that the firm's yearly accounts will be made up as at the usual date—i.e., Dec. 31. The new firm will be assessed under Schedule D in the ordinary course for 1946-47 (presumably on the basis of the profits for the year to Dec. 31, 1945), excluding the £300 which is assessable under Schedule E, and Alpha will be liable to account to the firm for his share, for twelve months, of that charge. In so far as an expense is allowable for income tax as being incurred in carrying on the professional work, the full amount as increased by the purchase tax is allowable. The question does not, of course, arise in respect of non-professional expenditure.

LETTERS, NOTES, ETC.

Civilian Employment for R.N. Sick Berth Staff

Surgeon Captain MONTAGUE H. KNAPP, R.N. (Retd.), writes: The Central Council, Royal Naval Sick Berth Staff Association, composed of Naval medical officers, was founded in 1933, the principal object being to advertise, by various means, the little-known fact that men of the Royal Naval sick berth staff are fully trained and experienced male nurses, who on return to civil life, after 12 or 22 years' service in hospitals and ships in the Royal Navy, are available for and desire civil employment. During the passing of the Nurses' Act, 1943, at the instigation of the Council, the position of these men was constantly brought forward by our Patron, the late Admiral Lord Keyes, and other Naval and medical members of both Houses, with the result that the original suggestions of the Council made to the Ministry of Health were conceded, viz: (a) Reopening of the List for registration, as "State Registered Nurses" for those qualified to register up to 1925, which, owing to the matter not being adequately promulgated to those abroad, many had failed to do. (b) That sick berth ratings with certain qualifications as to service, etc., were to be recognized as "Service Trained Male Nurses," and registered as such. Unfortunately, owing to death, ill-health, and age, none of the original founders, or officers of the Council, are now available to carry on the work, and medical officers, R.N. and R.N.V.R., active or retired, are urgently required to fill the vacant offices, and I wish to appeal to all who are interested and willing to help to communicate with me, c/o Medical Department, Admiralty, 64, St. James's Street, London, S.W.1.

Facial Palsy Accompanying Acute Mastoiditis

T. K. R. OGILVIE writes: Please allow me to make a small correction in my article published on Aug. 24 (p. 263). The first line of the description of Case 4 should read "Mr. A., aged 36, attended his practitioner," instead of "attended hospital." I would also like to add that one of my objects in publishing the report was to warn practitioners of this pitfall and to point out one of its presenting symptoms, persistent slight deafness.

Pethidine as a Drug of Addiction

Dr. A. HARBOUR (London, S.W.1) writes: It may not be generally known that pethidine may cause addiction in as serious a degree as the more common drugs associated with this condition. A case seen by me lately brings this out clearly. The patient, a man of colour, was under my care for some 36 hours while being held by the police on a charge unconnected with his addiction. He had been a heroin addict but had been cured by the substitution of pethidine and no longer took the former drug except on rare occasions. On the other hand he needed three injections a day of 400 mg. of pethidine to keep under control. Deprived even for a very short time of his drug he behaved in the normal way of an addict deprived of his "shot." Two points arise from this case. First, that physicians who relieve an addiction to one of the common drugs by substituting pethidine run the risk of a mere alteration of the addiction and a continuance of the misery and vice that goes with such a condition; and secondly, that the present position relating to the

supply of pethidine whereby an addict can have a prescription repeated *ad lib.* or can obtain the drug without a prescription or signing the poison book at a chemist is unsatisfactory.

** We understand that pethidine has been recommended for insertion in Schedule I but is not yet legally included, although pharmacists by common consent now act as if it were on Schedule I.

Experimental Helminthic Infection

Mr. E. L. TAYLOR writes from the Veterinary Laboratory, Ministry of Agriculture, Weybridge: May I call attention to inaccuracies in a reply to a question on experimental helminthic infection which appeared in the *Journal* of Aug. 31. The writer of the answer appears to be unaware of the highly specific nature of the host requirements of most helminths. Although some members of the genus *Taenia* occur in rabbits, in their larval stages only, *Taenia solium* cannot infect that host at any stage in its life history. If your correspondent wishes to infect rabbits with adult tapeworms he must interest himself in members of the genus *Cyttospora*, the larval stage of which is spent in the body cavity of certain species of free-living mites. Nor can an infection with *Enterobius vermicularis* be maintained in rabbits. These animals do, however, become infected with more or less closely allied species that may have some value for the purpose of testing substances thought to possess anthelmintic activity against *Enterobius*. The demonstration of the anthelmintic activity of a substance against these allied species of worms would not of necessity indicate any action against *T. solium* and *E. vermicularis* but would be indicative of the need for specific trials on those two parasites themselves.

** We are informed that the experimental infection of rabbits with *Taenia solium* and with *Enterobius vermicularis* for which a technique was asked by a correspondent is unlikely to prove successful because neither of the parasites occurs naturally in their hosts, nor have previous experimental efforts proved positive. *Taenia solium* has become exceedingly rare not only in this country but elsewhere in Europe. It is, however, fairly common in Cyprus and in South Africa, while the occurrence of cerebral cysticercosis in troops who have been stationed in India indicates that it is not uncommon there. Rats and mice harbour several species of oxyurids which could be used for experimental purposes more readily than *Enterobius vermicularis*, while there are several species of *Taenia*, closely related to *Taenia solium*, in dogs and cats available for experimental study.

Rash After Penicillin Lozenges

Dr. D. P. WHEATLEY (Watford) writes: Reactions to penicillin are rare; and a reaction to penicillin lozenges has not, so far as I know, been previously reported. The following case, therefore, may be of interest. A girl aged 22 came to me with a sore throat. On examination her tonsils were only slightly inflamed, and she was sent to bed with a box of penicillin lozenges with instructions to suck one two-hourly. I was called to see her again in a few days' time because she had been unable to continue with the lozenges, owing to a rash which appeared on her cheeks and upper part of her chest each time she sucked one. This appeared about 20 minutes after a lozenge, and was accompanied by a hot, tingling sensation of the affected skin. The rash was red and blotchy, somewhat resembling that of chicken pox. It was irritable and faded within 20 minutes. An interesting point was that the girl had on a previous occasion sucked gelatine penicillin pastilles with no ill-effect. The rash was presumed to be an allergic reaction, probably due to an impurity in the lozenges.

Journals and Textbooks Wanted

Dr. A. TUDOR HART writes from the Ministry of Pensions Hospital, Dunston Hill, Gateshead, 1: The International Brigade Association has received urgent requests from former medical officers of the I.B. Medical Service in the Spanish War, now at last working once more in their own countries, for current issues of medical journals. Would some of your subscribers be willing to forward their *British Medical Journal* regularly for a year? If so, will they please write to the secretary, International Brigade Association, 14, Red Lion Square, London, W.C.1, who will let them have a name and address. We have other former colleagues still working in China, to whom we should especially like to forward recent and expensive surgical textbooks. May we also appeal for some donations for this object? They should be sent to the same address, marked "Medical Textbook Fund."

Apology

Mr. GEORGE BANKOFF writes: I very much regret that owing to my book *Plastic Surgery* being written and published during the war years I could not obtain permission from Prof. Francis Burica of Prague to reproduce three of his cases published in his book *Chirurgia Plastica* (1935). They are: (1) A case of Italian method in nasal plastic, p. 190-191; (2) repair of a cheek defect, p. 266; and (3) reconstruction of thumb, p. 353, a, b, and c. These illustrations will be replaced by original photographs in future editions.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 21 1946

THE B.M.A. AND TRADE UNION LAW A FACTUAL STATEMENT

During the period of reconstruction which followed the war of 1914-18 there arose among a section of the medical profession demand for the reorganization of the Association. The advocates of this policy contended that the Association was organized on the wrong lines and that to be really effective the body representative of the profession should modify its constitution to become a registered trade union. The decision which some local authorities have taken to introduce a "closed shop" principle following the repeal of the Trade Disputes and Trade Unions Act, 1927, may revive the controversy of twenty-five years ago.

With the repeal of the 1927 Act it ceases to be unlawful for local or other public authority to make it a condition of employment that members of its staff should belong to a trade union. A few local authorities are imposing some such conditions. In one case it has been resolved that members of the staff should be required to belong to a trade union or to an appropriate professional organization. In another the local authority's resolution referred quite simply to membership of a trade union. In the debate on the Second Reading of the Bill which proposed the repeal of the 1927 Act, the Minister of Labour (Mr. Isaacs) said: "If a local authority gets the power saying they desire their workers to belong to a trade union, it is only sense that they should be able to say which unions they should join."

Approximately 80% of the doctors of the country belong to the British Medical Association, the body recognized by the Government and the Associations of local authorities as the governing body for the medical profession. Further, the Association is recognized by the Trades Union Congress as representative of the medical profession, a recognition which has expression in the Joint Committee of the B.M.A. and U.C.

The British Medical Association is not a trade union. It is a limited company with the licence of the Board of Trade to omit the word "limited" from its title, being an association formed for scientific purposes and not for profit. Its primary object is "to promote the medical and allied sciences and to maintain the honour and interests of the medical profession." Its Memorandum of Association provides that "the Association shall not support with its funds any object, or endeavour to impose on or procure to be observed by its members or others any regulation restriction or condition, which if an object of the Association would make it a trade union."

A trade union, for the purposes of the Trade Union Acts, 1711-1913, is any combination, whether temporary or permanent, the principal objects of which under its constitution are "statutory" objects. "Statutory objects" means:

- (i) the regulation of the relations between workmen and masters, or between workmen and workmen, or between masters and masters, or
- (ii) the imposing of restrictive conditions on the conduct of any trade or business and also
- (iii) the provision of benefits to members.

Opinions of Counsel

In 1919 the opinion of Counsel was sought as to whether the Association could be registered as a trade union. Mr. F. Gore-Brown, K.C., an acknowledged authority on company law,

and Mr. H. H. Slessor (later Lord Justice Slessor), who was at that time the author of the latest book on the legal position of trade unions and standing counsel to the Labour Party and to many trade unions, expressed the opinion that the Association could not be registered as a trade union while it remained a company registered under the Companies' Acts. These eminent legal authorities stated that, to fulfil the wishes of the advocates of medical trade unionism, it would be necessary for the Association to be wound up and for its members to form themselves into a new association and to seek to register that body under the Trade Unions Acts. The alternative would be for the Association to continue to exist for certain purposes, but for such of its members as see fit to form a new association to take over such of its functions as deal with restrictions imposed upon the practice of the profession and for this new association to seek registration as a trade union.

In 1946 when the repeal of the Trade Disputes and Trade Unions Act, 1927, was proposed by the present Government, the Association again sought legal advice. Mr. Cecil Havers, K.C., and Mr. M. L. Gedge expressed views identical with those expressed by Counsel in 1919. They added, however, that if it were desired that the Association should be wound up and a new body formed as a trade union which all the members of the Association could join, it would be impossible to transfer the assets of the Association to the new body, those assets in a winding up of the Association belonging, in the opinion of Counsel, to its members.

To sum up, the Association, even if it so desired, could not become a trade union without completely reconstructing itself and the objects as expressed in its present Memorandum of Association, the reasons being:

- (i) its principal objects under its constitution are not the "statutory objects" specified in the Trade Union Acts;
- (ii) it is a company registered under the Companies' Acts and the registration of any trade union under the Companies' Acts is declared void by Section 5 of the Trade Union Act, 1927, and Section 382 (7) of the Companies Act, 1929.

Counsel expressed the view that members of the medical profession are neither masters nor workmen within the meaning of the Trade Unions Acts. The medical profession could not satisfy the first of the "statutory objects," namely, the regulation of the relations between workmen and masters, etc. The only effective "statutory objects" which could be adopted would be the imposing of restrictive conditions on the conduct of their business and the provision of benefits to members. These would have to be the *principal* objects under the constitution of a medical trade union. Thus, the main question is whether a body representative of doctors can properly adopt as one of its *principal* objects the imposition of restrictive conditions on the professional work of its members. For example, can it properly withdraw its services from the public? For the imposition of restrictive conditions to be one of the objects would not suffice; it would have to be a *principal* object to satisfy Trade Union Law. If not, then the trade union method of organization is inappropriate to it.

The decisions which some local authorities have taken requiring their employees to belong to a trade union raise interesting and important questions in relation to medical practitioners working in the Public Health Service. A number of these medical officers are members of the National Association of Local Government Officers (N.A.L.G.O.) and in some cases, at all events, membership of that body may satisfy the local authority's requirements. Under Section 2 (3) of the Trade

Union Act of 1913 an unregistered trade union may obtain a certificate from the Registrar of Friendly Societies that the union is a trade union within the meaning of the Act, provided that it can satisfy the Registrar that the principal objects of the union are "statutory objects" and that the union is actually carried on for those objects. N.A.L.G.O.'s position is that it is certified by the Registrar as satisfying the "statutory objects" but has not proceeded to register as a trade union and at its annual conference this year decided not to seek affiliation with the Trades Union Congress. It would appear that where a local authority officer is merely required to become a member of a trade union, membership of N.A.L.G.O. would satisfy the requirement; where, however, the local authority specifies a registered trade union or a trade union affiliated to the Trades Union Congress, membership of N.A.L.G.O. will not suffice. If the object of a local authority is to secure that the medical members of its staff belong to the body which is representative of the profession as a whole and which is recognized by the local authorities through their associations as the negotiating body for the medical profession, this would be satisfied by requiring membership of the British Medical Association. Whether this is in the interest of the public, the local authorities, or the medical profession is not dealt with in this factual statement of the position of the Association in relation to Trade Union Law.

HEARD AT HEADQUARTERS

Tribute to General Practitioners

In the bestowal of praises for work done in the war the civilian doctor has not been a conspicuous recipient, nor, probably, would he wish to be, when all served and endured so well. But in his statement on the work of the medical department of the Ministry of Health during the six years of war, published on Sept. 12, Sir Wilson Jameson, the Chief Medical Officer, does make generous recognition of general practitioners, especially those senior practitioners who, without proper rest or holiday, carried on even to breaking point. By the end of 1942 the majority of the doctors remaining in civil life were over fifty, and more than 8% were over seventy. These ageing men, their sleep, particularly in London and other targets of enemy attack, more than usually interrupted by attendance at "incidents," and in many cases by the bombing of their own houses and surgeries, carried on under a steadily increasing strain as more and more of their colleagues and neighbours were called up. Sir Wilson reminds his readers that the normal inflow of new practitioners was completely diverted; even those found unfit for the fighting Services were almost all absorbed by the hospitals, while death and retirement and breakdown continually depleted the remaining civil ranks. These men had also to undertake many additional duties. They gave part of their time to E.M.S. and other hospitals, they took charge of first-aid posts under civil defence schemes, and trained nursing and other staff. During air raids they attended at the posts and treated casualties. The recruiting boards and the "works doctor" service in the munition factories were almost entirely manned by civil practitioners, who also furnished thousands of medical officers for the Home Guard.

In the middle of the war there was one general practitioner to 3,000 people. "The general practitioner," says the Ministry of Health report, "forms the front line of medicine; upon his skill and devotion much depends, and no small share of any credit that the medical services deserve for this maintenance of the public health during six years of war should fall to those general practitioners who, in such difficulties, carried on, and to those—not a few—who died in harness."

The Medical Officer of Health Too

Sir Wilson Jameson includes in his tribute the medical officers of health for their work and their sufferings. Their sufferings especially because their cherished plans for the

development of peacetime services were everywhere interrupted. Their real work had to take second place to the organization of emergency services, but how well they did that! Planning the development of casualty services, including much local organization of the emergency hospital scheme, had become a heavy burden before war began, and under aerial bombardment these services were brought to a high pitch of efficiency. The evacuation scheme produced large medical problems for the medical officer, both in evacuation and reception areas, and these were met with resource and skill. One after another additional burdens were placed on the medical officer's shoulders—medical problems of the post-raid services, emergency maternity homes, sick-bays for evacuees, gas contamination schemes, provision of day nurseries, and many others, and all this extra load had to be carried with a steadily declining staff. "Despite this the health services have been maintained and in many ways have advanced, and the credit for this achievement should be given to those who have been so largely responsible for it—the medical officers of health." It is revealed that by the end of 1943 there were 376 whole-time public health medical officers serving with the Forces, representing 47% of the total fit recruitable male practitioners in the public health service, and just over 50% of the recruitable women practitioners.

A Fight is On

The Insurance Acts Committee met in fighting mood the other day, and there was general satisfaction that the opening of a conflict, which seems inevitable, with the Ministry of Health should take place on ground, not indeed of the Committee's choosing, but so favourable to their side and on an issue so simple that the public and those of the profession who are not politically-minded can readily appreciate what is at stake. The issue is the refusal of the Minister to apply in its completeness the Spens report to the remuneration of insurance practitioners. Of the relevance of that report to insurance practice there can be no doubt in the minds of those who know the history of the subject. The first proposal which led to the setting up of the Spens Committee emanated from the Ministry of Health, and representatives of the Ministry attended a meeting of the Insurance Acts Committee to put it forward. It linked up with the assurance of the Minister of that time that the whole subject of the payment of the general practitioner should be approached anew "from the ground up"—an assurance given to a deputation from the I.A.C. which waited upon the Minister. The present Minister refuses to discuss the application of the report to the current insurance capitation fee unless the whole matter of remuneration under the future National Health Service is discussed at the same time, and neither the Insurance Acts Committee nor any other body representing the profession has any mandate at present to discuss that. Meanwhile he offers something less than half the addition which the Spens Report, as the I.A.C. reads it, recommends.

The forty or fifty members of the I.A.C., drawn from insurance practice in all parts of the country, show a quick appreciation of the salient points on any issue presented to them which would be bewildering to a visitor who knew little about insurance practice. It will not be easy even for Mr. Bevan to get the better of them, and on this matter they are unanimous. Their chairman follows the plan of asking every member of the committee to give his own views and the views, as far as he can, of those he represents, and the result on this occasion was a unanimity in support of the resolute action proposed which was far more impressive than might have been secured by a mere show of hands. A report of the meeting held on Sept. 5 appeared in last week's *Journal* at p. 395, and was followed by a note on the capitation fee.

The restrictions on admission to the list of National Health Insurance panel practitioners, which were introduced in Northern Ireland in 1942 for the protection of the insurance practices of doctors absent by reason of service in His Majesty's Forces, were removed on Aug. 31. The effect of this step is that once again any practitioner resident in Northern Ireland will normally have the right to have his name included in the list of insurance practitioners.

Correspondence

N.H.I. Capitation Fee

SIR,—Despite the unanimous recommendation of the Insurance Acts Committee that a capitation fee of 12s. 6d. as from an. 1, 1946, is grossly inadequate, but that they would be repared to consider a fee of 15s. as from that date, Mr. Bevan has already issued instructions to Insurance Committees to carry out his original suggestion. He has, in fact, deliberately spat in our faces in a manner which Mr. George Bernard Shaw must surely envy. A "show-down" must come. Why not have it now, regardless of the proposed National Health Service? My only criticism of the letter of Dr. Pybus (*Supplement*, Sept. 7, p. 80) is the proposed delay until April 1 next. With intensive activity we could have our resignations in the hands of the Insurance Committees within the next month or six weeks.—I am, etc.,

Preston

L. F. UNSWORTH

Absent Practitioners' Scheme

SIR,—With reference to the letter by Dr. Thos. Savage (*Aug. 31, p. 72*), may I suggest that even more important than a list of those who subscribed to the absent practitioners' scheme would be a list of those who loyally carried out their engagement not to accept his patients until a year after his return. My experience suggests that this would be considerably shorter.—I am, etc.,

Blackpool

J. HESKETH-BEASLEY

A Register of Unemployed Doctors

SIR,—So much has been written recently concerning unemployment among medical men that I feel the time has come for some constructive proposals which may assist in dealing with this very real problem. May I suggest, as a temporary measure, that some simple form of register be formed by the B.M.A.—on the lines of the Ministry of Labour or Disabled Persons—on which any doctor unemployed for, say, four weeks or more could enter his name if he be willing and fit to take up work.

This register would be available to doctors who require assistance, to hospitals, and to medical agencies. By centralizing this work we should know at any time the number of medical men unemployed and the magnitude of the problem we have to face.—I am, etc.,

Southport

JOHN H. HANNAN.

Medical Unemployment

SIR,—I have been reading with great interest the letters concerning the plight of demobilized doctors, and am rather surprised at the lack of initiative they show. They balk at the price of house and practice, but should treat the two things as separate transactions. The practice is goodwill and has paper value only. The house is material property and remains so. The younger men must pay the prevailing market price for a house, like everyone else, and it is unlikely that the values will fall for ten years or so and not so very much then. Also they should remember that the outgoing practitioner must live somewhere and he will have to pay the market price too.

What amazes me most is their unwillingness to buy a practice. Unless they do so they face two years' semi-unemployment until the new Service begins, then say two years as assistant, and after that probably four or five years in building their practice up to a full income—a total of eight or nine years. Apart from that they will find that the majority of vacancies will be in the unattractive areas and even then they will still have house-hunting to do.

Now take the other point of view if they buy a practice. A pre-war practice of £2,000 gross would cost £4,000. Nowadays it can be got for £3,000, which in pre-war values equals £1,500 a year gross. Any averagely good man should be able to prevent a £2,000 wartime gross from falling to £1,500. Out of that he should be able to repay his practice within six years and be at his maximum at least two years before the man who wants everything handed him on a plate. Further advantages

are that he has chosen his own district and has had his house all the time. Also he would have a claim on the compensation fund morally and probably legally.

I was qualified for eight and a half years before I could borrow money to buy a practice; for ten and a half before I could marry; and for fourteen years before I got the practice paid off. The impression I get from the letters you publish is that the younger men expect me to like my savings being confiscated, and at the same time to provide them with employment during the interim period before the new Service, while they sit back and take their ease with their families, acquired at a much earlier stage than ever I could manage.

A final word of warning—don't accept inferior conditions in a Service in which the younger generation have to spend all their working lives.—I am, etc.,

Middlesex.

"RAIHER DISGUSTED."

SIR,—Could not members of the B.M.A. who are in employment contribute according to their means towards a special fund to give immediately financial aid to those out of work through no fault of their own? Much of the unemployment so far as I can see is a direct result of the Health Service Bill which may or may not become law in the comparatively distant Spring of 1948. Both ex-Service and other doctors are affected. Living on a diminishing capital is an unpleasant experience particularly for a married man, as "Ex-R.N.V.R." points out. He is a desperate able-bodied medical man who would apply for help to any of the existing medical benevolent societies.

I may say that I have followed this correspondence with peculiar interest having only recently received an appointment myself after more than six years' military service. My four months' release leave was spent in a fruitless and heart-breaking search for what I considered to be a suitable job, and almost two more months went by before I got one. It was, I can assure you, Sir, a most worrying time. In conclusion, to take away any possible savour of charity, I suggest that to those who wish it the money could be advanced as a loan without interest, to be repaid in better times to a recognized medical benevolent society.—I am, etc.,

"EX-LIEUT.-COL. R.A.M.C."

Dr. F. HARMAN VOLLAM writes from Alcechurch: May I, through the medium of your columns, thank all the doctors who have written to me and advise them that the post has been filled. The response has been overwhelming, but I will write to them all as soon as possible.

H.M. Forces Appointments

ROYAL NAVY

Surg. Capt. C. H. M. Gimlette has been placed on the Retired List.

Surg. Lieut.-Cmdr. G. S. Thoms to be Surg. Cmdr.

ROYAL NAVAL VOLUNTEER RESERVE

Temp. Acting Surg. Lieut.-Cmdrs. A. B. Burns, H. S. A. Corfield, R. C. R. Gethen, and C. L. G. Pratt, O.B.E., to be Temp. Surg. Lieut.-Cmdrs.

Temp. Surg. Lieuts. E. A. Bissen and D. J. MacMillan to be Temp. Surg. Lieut.-Cmdrs.

Prob. Temp. Surg. Lieuts. G. E. Dixon, A. A. Donaldson, W. D. MacKenzie, J. D. Medhurst, P. J. W. Menck, F. C. O'Duffy, G. E. Pögel, K. E. E. Read, J. Stafford, W. J. Steadman, D. D. Stern, R. V. Sturton, G. N. Tave, G. R. Widdell, D. E. Yates, A. D. C. Young, J. L. Fluker, E. W. R. Alderman, K. R. Keay, J. D. S. Knight, P. H. McGregor, C. G. Martin, and T. Smart to be Temp. Surg. Lieuts.

ARMY

Col. E. W. Wade, D.S.O., O.B.E., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brig.

Col. G. D.R. Carr, M.C., late R.A.M.C., having attained the age of retirement, is retiring on the Active List supplementary

ROYAL ARMY MEDICAL CORPS

Lieut.-Col. A. G. ... O.B.E., to be a Comm. Surg. and has been awarded the Medal of Merit.

Association Notices

The Katherine Bishop Harman Prize

The Council of the B.M.A. is prepared to consider an award Katherine Bishop Harman Prize of the value of £75 in The purpose of the prize, which was founded in 1926, is courage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child-bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the prize. Any medical practitioner registered in the British Empire eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in but will be offered again in the year next following this decision and in this event the money value of the prize on the occasion question will be such proportion of the accumulated income as the Council shall determine. The decision of the Council will be

Each essay must be typewritten or printed in the English language must be distinguished by a motto, and must be accompanied sealed envelope marked with the same motto and enclosing candidate's name and address. Essays must be forwarded so as to reach the Secretary, to whom all inquiries should be addressed: B.M.A. House, Tavistock Square, London, W.C.1, not later Dec. 31, 1946.

Diary of Central Meetings

OCTOBER

23. Wed. Special meeting of Council, 10 a.m.

Branch and Division Meetings to be Held

NORTH WALES BRANCH.—At Free Library, Dolgelley, Wed., Sept. 25, 2.30 p.m., 97th Annual Meeting. Dr. R. W. Edwards: Paediatrics.

PADDINGTON DIVISION.—At County Hall, Room 140, Westminster Bridge, S.E., Tues., Sept. 24, 3 p.m. Papers by Mr. R. Lov Ph.D., Prof. F. J. Browne and L. S. Penrose: Causes and Prevention of Prematurity. A discussion will follow. All medical men are invited.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) Week-end course Ear, Nose and Throat Diseases, at Metropolitan Ear, Nose and Throat Hospital, Saturday and Sunday, Sept. 28 and 29; (2) course in Gynaecology (for general practitioners) at Samaritan and St. John's Hospitals, daily from Oct. 7 to 12; (3) week-end course in Rheumatism at Rheumatic Unit, St. Stephens (L.C.C.) Hospital, Saturday and Sunday, Oct. 26 and 27.

A course of lectures in skin diseases will be held at the London School of Dermatology, St. John's Hospital for Diseases of the Skin, 5, Lisle Street, Leicester Square, W.C., on Tuesdays and Thursdays at 5 p.m. from Oct. 1 to Dec. 12.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Mr. Brown: The Modern Treatment of some Diseases of the Ear, Nose, and Throat.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Wed. 8 p.m. Dr. J. B. Gaylor: Electroencephalography in Retinal Disease.

LIVERPOOL HEART HOSPITAL, Oxford Street.—Lectures, etc., Monday to Friday, inclusive, 3.30 p.m.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender, and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

ARDEN.—On September 11, 1946, at Lyncroft Nursing Home, Gerrards Cross, Bucks., to Kathleen (née McCaffrey), wife of G. P. Arden, F.R.C.S., a daughter—Susan Anne (sister for Mary).

COOPER.—On September 9, 1946, at Queen Victoria Hospital, Mortcote, W. Hazel (née Ratcliffe), wife of W. A. Bruce Cooper, M.B., B.S., a daughter.

ELLIS JONES.—On September 4, 1946, at Queen Charlotte's, to Rosemary (née Case Morris), wife of Dr. E. Ellis Jones, M.B., B.S., a daughter—Madeleine Carleton (premature, both well).

HARVEY.—On September 2, 1946, at Hitchin, to Mollie (née Lambert), wife of W. Cdr. E. Bruce Harvey, R.A.F.M.S., a daughter—Sally.

HUSTON.—On September 7, 1946, at Elsie Inglis Memorial Hospital, Edinburgh, to Winston, wife of Lt.-Colonel John Huston, R.A.M.C., a daughter.

NICOL.—On June 27, 1946, at Lowestoft, to Dorothy, wife of Dr. Thomas Steven Nicol, a son—Adrian.

MARRIAGE

WELLS—BEATON.—On August 17, 1946, at Streatham, Flying Officer P. W. Wells, of Tooting, S.W.17, to Mary Aldyth Beaton, of Streatham, S.W.16.

DEATH

DE PENNING.—On September 19, 1945, Lily Beatrice, beloved wife of Herbert Clement De Penning, M.R.C.S., 38, Milton Road, Portsmouth.

War Subs. Lieut.-Col. J. V. McNally has retired on retired pay and has been granted the honorary rank of Col. (Substituted for the notification in a Supplement to the London Gazette dated Aug. 13.) Lieut.-Col. C. G. G. Keane, O.B.E., having reached the age for retirement, is retained on the Active List supernumerary.

War Subs. Majors J. J. Sullivan, P. H. Ball, and P. Coleman to be Majors.

Capt. (War Subs. Major) R. H. Baird has retired and has been granted the honorary rank of Lieut.-Col.

Capt. (War Subs. Major) G. B. Heugh, J. C. Watts, M.C., J. McGhie, T. M. Fowler, O. W. W. Clarke, G. M. Robertshaw, G. M. Curtois, G. H. H. Dunkerton, D. Matheson, J. C. Babbage, and Capt. J. A. Manifold, R. A. Smart, E. W. O. Skinner, D. G. Lewis, J. E. C. Robinson, K. P. Brown, E. Gareh, G. F. Valentine, C. McNeil, R. L. Townsend, W. G. Macfie, M. M. Medine, M.B.E., S. Ward, A. J. N. Warrack, M.B.E., S. F. Cranston, W. Windsor, W. A. McD. Scott, J. Mackay-Dick, J. C. Lambkin, P. D. Stewart, T. A. Pace, O.B.E., S. O. Bramwell, R. A. Bond, W. M. Stewart, D. D. Maitland, G. F. Edwards, M.B.E., H. C. Jeffrey, H. J. A. Richards, J. B. Plews, T. G. S. James, J. F. D. Murphy, V. J. Keating, T. McEvel, R. M. Hector, A. Crook, A. W. Box, D. W. Bell, T. G. A. L. Warrington, P. R. Wheatley, D.S.O., R. L. Macpherson, M.B.E., D. A. Ireland, and J. S. F. Watson to be Majors.

Capt. O. Jordan has retired and has been granted the honorary rank of Major.

Capt. D. J. R. McConvell has been appointed to a permanent commission.

Short Service Commissions.—War Subs. Capt. J. L. Fison and D. J. R. McConvell, from R.A.M.C., Emergency Commissions, have been granted Short Service Commissions in the rank of Lieut., and to be Capt.

Lieut. R. Andrew to be Capt.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Subs. Major T. F. Strang has relinquished his commission and has been granted the honorary rank of Major.

War Subs. Capt. J. B. Tracy and S. E. Bolton have relinquished their commissions on account of disability and have been granted the honorary rank of Major.

War Subs. Capt. C. W. Stewart has relinquished his commission on account of disability and has been granted the honorary rank of Capt.

To be Lieuts: J. L. Carson, A. Guedatarian, A. M. Knox, C. C. Lewis, M. J. G. Lynch, J. M. Moore, W. M. McIntyre, D. R. Murley, A. B. Ostrovsky, T. Sanderson, P. G. Somerville, and R. W. C. Kelly.

WOMEN'S FORCES

EMPLOYED WITH THE R.A.M.C.

War Subs. Capt. (Miss) M. W. Hughes has relinquished her commission on account of disability and has been granted the honorary rank of Capt.

(Miss) Mary R. Anderson and (Miss) Letitia M. Camilleri have been granted commissions in the rank of Lieut.

ROYAL AIR FORCE

Group Capt. T. J. Thomas has reverted to the retired list.

Wing Cmdr. P. H. Perkins has retired at his own request.

Squad.-Ldr. (Temp.) D. W. Browne to be War Subs. Squad.-Ldr.

ROYAL AIR FORCE VOLUNTEER RESERVE

Fl.-Lieut. (Temp. Squad.-Ldr.) S. Rogers has resigned his commission retaining the rank of Squad.-Ldr.

To be Squad.-Ldr. (Emergency): L. E. Jones.

To be Fl.-Lieut. (Emergency): A. F. McLean, N. F. Morris, and G. Wraith.

To be Flying Officers (Emergency): D. Anthony, W. H. R. Auld, S. I. Beswick, J. L. Braithwaite, T. D. Brick, J. H. Gibson, J. D. Glanville, T. Harvey, E. P. G. Houssemayne du Boulay, J. D. Jack, A. T. Johnson, J. R. G. MacKetsack, M. Mattinson, K. W. Oldham, D. Richardson-O'Keefe, W. Ritchie, E. Shenken, R. A. Sladden, G. P. Sutherland, and M. Thomas.

INDIAN MEDICAL SERVICE

EMERGENCY COMMISSIONS

Temp. Major C. H. Phillips has relinquished his commission and has been granted the honorary rank of Major.

Capt. L. J. Michael has relinquished his commission and has been granted the honorary rank of Capt.

RETURN TO PRACTICE

The Central Medical War Committee announces that the following have resumed civilian practice: Dr. Kenneth O. Black, F.R.C.P., at 27, Weymouth Street, W.1 (Langham 3336); Mr. Bryan Murless, F.R.C.S., at 803, Acutus Arcade, Durban, S. Africa; Mr. R. W. Nevin, F.R.C.S., at 53, Harley Street, W.1 (Langham 1077).

LONDON SATURDAY SEPTEMBER 28 1946

SOME VULGAR ERRORS IN REGARD TO GOITRE

BY

J. W. LINNELL, M.D., F.R.C.P. GEOFFREY KEYNES, M.D., F.R.C.S.

AND

J. E. PIERCY, F.R.C.S.Ed.*

During the past generation the importance of goitre as a fount of many unsuspected ills has become more and more recognized. It is but natural that new advances in any field of medicine should only gradually become known to the profession at large, and goitre is no exception to the rule. It is with the object of discussing some of the commoner fallacies concerning its dangers, diagnosis, and treatment that we who have had the opportunity of studying the condition over a long period of years venture to write this article. We would say it was the intention of the late Cecil Joll, who worked at our clinic throughout the war, to collaborate with us in its production, and that, though death prevented his doing so, he had already expressed his complete approval of the plan and the opinions embodied in it.

1. That, though goitres which are patently toxic need treatment, the great majority of the rest are harmless or practically harmless, will probably remain so, and may safely be left untreated.

By a curious coincidence an article in the *Journal of the American Medical Association*, entitled "Potential Dangers of Nontoxic Goiter," by Cole, Slaughter, and Rossiter (1945), was published almost simultaneously with one written by Linnell (1945) in the *Practitioner*, entitled "The 'Harmless' Goitre," which ran on much the same lines. Both drew attention to the danger of such complications as (1) the development of thyrotoxicosis with its many and multifarious complications, (2) carcinomatous changes, and (3) pressure through increasing size. These complications are discussed in greater detail below. In the discussion which followed the reading of the American paper one speaker stressed the risk of sudden pressure by haemorrhage into the substance of the gland—a somewhat rare complication—though this point had not gone unnoticed by us.

1. *Thyrotoxicosis*.—The common belief that comparatively few goitres become toxic has no foundation in fact. The American workers we have mentioned believe that no less than 50% of all non-toxic goitres become toxic if left untreated, and add that, in view of the narrowness of gradation between non-toxic and toxic nodular goitres, this figure may well be too low. We, for our part, believe with Hertzler (1936), and many other workers in different parts of the world, that by the time early middle life is reached goitres without some evidence of associated toxicity are rare. It would seem that most medical practitioners recognize only the gross and more easily discernible symptoms and signs of thyrotoxicosis; those of less degree go unrecognized or are disregarded as being of little importance. These symptoms, it may be said, often can only be detected by careful observation, for they may amount to no more than some of the following: lassitude, minor or occasional palpitations, slight irritability or emotional instability, loss of weight, irregular sweatings or feelings of heat, a small rise of the resting or, better, sleeping pulse rate, a fine digital tremor, the suspicion of a stare due to retraction of the upper lids, and an almost imperceptible difference in the size of the

palpebral fissures. The fact that there may be phases of exacerbation and intermission of the symptoms does not make their discovery easier. As to their being of little consequence, it cannot be too strongly emphasized that they are of the greatest importance. Unfortunately, it is not yet generally appreciated that next to acute rheumatism toxic goitre is the most fruitful cause of auricular fibrillation, and goitres of apparently such mild toxicity as we have described are, without any doubt whatever, often responsible for it. In this connexion it may be well to add that occasionally auricular fibrillation has been, in our experience, apparently the very first sign of toxic change. Other signs were no doubt there, but were so slight as to escape observation. Toxic goitres, whatever the degree of toxicity, can also cause auricular flutter, both paroxysmal and established, and auricular paroxysmal tachycardia; but these are relatively rare complications.

To exemplify the frequency of auricular fibrillation as a complication of toxic goitre Papp (1945) says that 20% of all patients with toxic goitre develop this symptom, and that, though it is exceptional under the age of 30 and uncommon between 30 and 40, it becomes increasingly frequent thereafter, so that 80% of all cases of thyrotoxicosis fibrillate after the age of 60. These figures are sufficiently arresting, and our only comment is that, as the significance of the milder degrees of thyrotoxicosis is more widely recognized, it will almost certainly be found that the total percentage of patients who develop fibrillation is considerably higher. Generally the fibrillation is at first paroxysmal and only later established—a matter, as we shall see, of considerable importance; and the fact that established auricular fibrillation is a forerunner of congestive failure must never be forgotten.

2. *Carcinomatous Change*.—American workers are evidently very much more concerned about this danger than we on this side of the Atlantic. In the article already referred to it is stated that no less than 7.2% of 523 non-toxic goitres of all kinds operated on were found to be carcinomatous, and that among single non-toxic nodules as many as 24% were so affected. Lahey, the chief of the famous clinic of that name, in the discussion which followed the reading of the article, insisted that neither the size of the goitre nor the age of the patient mattered; that he had known a boy of 9 die of carcinoma of the thyroid, and that he had had several patients with the same condition at 12, 13, and 14 years of age. This would fit in with the belief held by many that most carcinomas of the thyroid derive from foetal adenomas: a belief, however, that is incapable of proof, as by the time middle life is reached the tumour has, as a rule, suffered so much change through growth and haemorrhages into its substance that it is impossible to be sure as to its original structure.

We must confess that we have so far seen no carcinomas in children, though several have occurred in quite young people. The majority have been in patients of middle life or later. Still, there are a considerable number of patients in this country whose goitres are allowed to become patently carcinomatous before they are deemed to be proper subjects for surgery; and we would insist that by the time the

* Members of the L.C.C. Hygiene Committee.

textbook picture of carcinoma of the thyroid is present the growth has penetrated the capsule and invaded the surrounding tissues, so that as a rule the hope of a surgical cure is past, even if by surgery and deep x-ray therapy life can often be prolonged for many years. It is lamentable to see, as we have seen, patients with widespread secondaries who have, over a long period of years, been urged not to worry about their goitres, and have continued to receive this advice even though they were steadily increasing in size and fixity and sometimes causing a sense of pressure or even pain. We would stress that tenderness on pressure is often an early sign of malignant change, and several of our cases have been diagnosed correctly on the basis of this observation. Unfortunately the innocent goitre, though usually painless, is occasionally painful; a haemorrhage, for instance, can very closely simulate malignancy; and as a rule it is only in the laboratory, after operation, that early malignant change can be definitely diagnosed.

3. *Pressure*.—Displacement, distortion, and narrowing of the trachea are some of the commonest findings in the examination of patients with large goitres, particularly of the nodular type, and more especially if there be retrosternal prolongations. Sometimes no symptoms result; in some patients, however, the goitre causes definite stridor and distress—possibly only on effort—or a mild dysphagia. A persistent irritating cough, again, may occasionally be the presenting symptom, while one of the earliest symptoms of all can be a choking sensation which awakes the patient. These symptoms are all due to chronic pressure, but a nodular goitre—even a foetal adenoma in a young subject—may occasionally be the seat of a sudden haemorrhage causing pain, swelling, and frightening sensations of suffocation. Death seldom follows, though this has happened once in our clinic.

II. That to diagnose toxic goitre it is necessary to find tachycardia

There is little doubt that the cardiovascular, nervous, and metabolic systems are all affected to some degree by toxic goitre, but sometimes, for an unknown reason, only one, or it may be two, of these systems are affected to any marked degree. Thus we have seen a number of patients with many of the classic symptoms of toxic goitre in whom the heart rate is little, if at all, increased over the period of observation. In this connexion it may be worth while to add that during the intervals between attacks of paroxysmal auricular fibrillation due to toxic goitre the heart rate may be normal or rarely slower than normal.

III. That loss of weight is a constant feature of toxic goitre

This again is not true. Maintenance, or even an increase, of weight is not very uncommon even in patients with primary toxic goitre, where loss of weight is a recognized cardinal symptom. As was pointed out in the previous section, the toxic process may miss, or almost miss, the metabolic system, and this may be the cause of the phenomenon. Sometimes a ravenous appetite, combined with a good digestion and efficient absorption, may in its effects counterbalance or even exceed—for a time at any rate—those produced by an increased metabolism. But doubtless there are other reasons, at present unknown to us. It has, by the way, been urged by Trotter and Eden (1941) that surgical treatment in plump patients with Graves's disease is attended with a greater risk to life and is less satisfactory than in the ordinary type of patient. This is not confirmed by our experience.

IV. That no goitre should be considered toxic unless the basal metabolic rate is found to be above normal

This would seem to be almost an article of faith among the profession as a whole, and perusal of the recent spate of papers on thiouracil has done nothing to weaken our impression.

Regarding the test, the late Cecil Joll was wont to say in his later years that, though it was the best laboratory test we had, it was "a poor best"; and with this opinion we fully agree. A test which accounts readings of 15 points above and below normal as "within normal limits" can hardly be regarded as satisfactory, and the fact that the same patient under apparently identical conditions can give very different readings on two

successive days shows how misleading single estimations may prove. We fully appreciate the far greater value of a "level" based on a large number of estimations made at short intervals; but, unfortunately, in this country the necessary finances and facilities are generally lacking. Again, even in definite thyrotoxicosis, exacerbations and remissions are, as we have already said, comparatively common, and during a period of remission—which may be long—the basal metabolic rate may be within normal limits. The point, however, which we especially wish to make is that in the very large and important group of goitres to which we have drawn attention, where the toxicosis is minimal and yet the danger of eventual auricular fibrillation is real, so little is the general metabolism affected as a rule that it is rare to find the basal metabolic rate significantly raised.

We have no desire to decry the occasional value of the test, but the longer our experience has become the greater emphasis we have tended to put on an appraisal based on a careful clinical examination. That a course of thiouracil in doubtful cases might provide valuable evidence for or against the presence of thyrotoxicosis occurred to us, as to others, soon after its introduction, and we have often used it for this purpose. It is as yet too early to speak definitely, but such a therapeutic test may possibly prove an adequate substitute for an estimation of the basal metabolic rate.

V. That iodine cures

We rarely see a new patient with toxic goitre who has not been taking iodine for weeks, months, or even years. There is no evidence whatever for the belief that this drug cures. Waller (1914), in the original paper on its use in Graves's disease published in the *Prescriber*, did not make this claim; nor has any authority done so since. Its beneficial results are, unfortunately, only temporary, and its use ought, in our opinion, to be restricted to the period immediately preceding, and possibly that immediately following, operation. It is doubtful indeed if, owing to its misuse, it has not been more of a curse than a blessing in the treatment of thyrotoxicosis. Through the widespread belief in its curative power operation has often been unduly delayed until heart complications, extreme emaciation, or even a psychosis have supervened.

VI. That treatment by deep x rays is a satisfactory alternative to surgery in toxic goitre

This belief is probably not so widespread as it once was, but it still persists. This little we would say on the subject: x-ray therapy is generally conceded to be of no value in nodular toxic goitre—and in this connexion it is well to realize that many goitres, which clinically do not appear, to be nodular, are found at operation to be of this type. Furthermore, as regards primary toxic goitre, Joll, who was extremely doubtful of the value of x-ray therapy, used to say that the radiologists who wrote so strongly in its favour seemed to forget that a large part of the gland was situated behind the trachea, so that irradiation powerful enough to destroy gland tissue in such a situation would almost certainly cause serious damage to the tracheal mucous membrane. In any event the results have, in our own experience, for the most part proved very disappointing. One of the most devastating criticisms of this mode of therapy was made by Dunhill (1935), an erstwhile member of our unit, when he stated that of 140 adults so "cured" no fewer than 118 were found to have established auricular fibrillation at a later date. In face of such a statement it would seem unnecessary to pursue the argument further.

VII. That the advent of thiouracil has removed the need for operation save to relieve pressure symptoms or for cosmetic reasons

This doctrine is being widely preached at the present time, and enthusiastic reports of the virtues of the new drug follow one another in the journals with an almost monotonous regularity. Even the writer of a leading article in the *Lancet* of April 14, 1945, declared, with regard to the question whether thiouracil should replace thyroidectomy as the standard treatment of toxic goitre, that there were strong indications that it might do so. From the first, voices have been raised protesting that the claims made for it are excessive and that various

langers attend its administration, but they have tended to be drowned in the chorus of approval. We soon felt it our duty to add our voices to those of the minority. To us it was deplorable that a drug, potent not only for good but also for evil, should be thrown on the market to be used indiscriminately and generally speaking without adequate supervision, until much more was known about the indications for its use, its limitations, and its dangers. That by preventing the final synthesis of thyroxine in the gland it can in most instances inhibit thyroid activity and so alleviate thyrotoxic symptoms, there is no doubt; that in patients in whom the toxicosis is temporary and self-limited it can maintain normal health till the attack is over appears likely; that already numbers of patients have been able to resume and maintain their normal activities as long as the treatment is continued, and that in a considerable proportion remissions can last for many months after a discontinuance of the treatment, is certain; but up to date there is no convincing evidence that it cures.

As matters stand it would seem that for its beneficial effects to be maintained it must usually be given for an indefinite period, since thyrotoxic manifestations almost always recur sooner or later after its discontinuance, and generally sooner. Furthermore, as Grainger, Gregson, and Pemberton (1945) point out, initial improvement is sometimes followed by relapse while the patient is still under treatment. Nor must it be forgotten that some patients prove recalcitrant, and that in 10 to 20% of those treated there are complications—some merely annoying, others frankly dangerous. This should soon damp the first enthusiasm, especially as the possible complications are many, and it would appear that their number grows with the growth of experience of the drug. Headache, nausea, and vomiting—usually transient, but occasionally so severe or prolonged as to cause discontinuance of the treatment—pyrexia, splenic enlargement, various rashes, adenitis, enlargement of the salivary glands, diarrhoea, jaundice, oedema, pains in the joints, leucopenia, thrombocytopenia, agranulocytosis, and myxoedema are some though not all of those which have been described. Of these a certain degree of leucopenia is usual, and in the large majority of patients has no serious import. Agranulocytosis is, however, in a different category, since it carries a high mortality. According to the latest American statistics it has occurred in over 2% of the patients treated whose records are available, and it is now known that it may develop with disconcerting suddenness, which is not necessarily dependent on the dosage and may not be presaged by a notable fall in white cells. As Cookson (1945) has pointed out, a long period of perfect tolerance to the drug may end in this or some other toxic reaction. It is argued that comparatively few deaths due to thiouracil have been reported to date, but with its wide use among practitioners, many of whom are unlikely to be able to make the difficult diagnosis of agranulocytosis, the number of deaths from this cause alone is almost certainly greater than that recorded, and, furthermore, we would suggest that a drug proved capable of causing severe damage not only to the haemopoietic system but also to the liver in certain patients treated for a short time is not unlikely to cause harm to all patients treated for a long time; and the warning given by Broders and Parkhill (1944) that "the thiouracil goitre is more of a cellular hyperplasia with mitosis very much in evidence and so, therefore, more comparable to a carcinoma," only adds to our apprehension. As to the effects of thiouracil on the size of the goitre, although many examples of primary toxic goitre have been described in which after long treatment there has been a marked decrease in size, occasionally the tendency is to an increase which, in our experience, may be amazingly rapid. Little, if any, decrease can be expected, of course, in nodular toxic goitres.

All this, however, is not to say that there is no place for thiouracil in treatment. From the first we have held with Lahey (1945) that it has a very valuable use in preparation for safer operation, if not as a method of cure; and now the conclusions reached by the American Council of Pharmacology and Chemistry (1946), based, as they are, on a survey of no fewer than 5,745 patients treated with it for various periods, would appear to prove us right. They are that available evidence shows that thiouracil can be recommended only in preoperative treatment and where operation is for any reason

contraindicated. Before the publication of this report, however, we had formed the opinion that surgery in good hands is greatly superior to thiouracil as a mode of treatment. It offers a prospect not only of rapid removal once and for all of the tumour and the manifest dangers connected with its presence, such as pressure, haemorrhage into its substance, carcinomatous change, and the not unimportant anxiety the mere presence of a tumour occasions, but also of a rapid disappearance of thyrotoxic symptoms. The risk of development of auricular fibrillation is practically removed, and where it is present there is good hope of a quick return to normal rhythm. Convalescence too is relatively brief. In addition we believe that in the end the mortality rate will be found to be lower.

VIII. That patients with auricular fibrillation and gross signs of congestive failure are too ill for operation

This, we find, is a fairly common belief in the profession. Yet we have seen scores of such patients not only come safely through the operation (sometimes done in stages) but even take on a new lease of active life and enjoy reasonable health for years afterwards. Admittedly the operative risk is greatest among these patients, but several who were apparently moribund have been saved. If, and only if, a marked degree of thyrotoxicosis is present is thiouracil indicated in the preparation of this class of patient, so far as our experience goes. Then it may prove to be of the greatest value.

IX. That the results of subtotal thyroidectomy in toxic goitre are usually unsatisfactory

Had we not heard this opinion of the value of the operation expressed on several occasions by postgraduate students we should not have deemed it worthy of inclusion in our list. We can only think that these observers have been unfortunate. The operation is regarded by thyroid surgeons everywhere as one of the most satisfactory. Dunhill (1934), for instance, found that 84% of 428 patients were able to live "approximately normal lives" after operation; Joll (1932) that 90% were able to return to a "full and active life" within three months of operation; and Keynes (1935) that nearly all patients operated on were enabled to live an approximately normal, instead of a semi-invalid, life, and the majority to assume full activity both physical and mental.

Nursing is generally recognized as one of the most arduous professions, and yet of some 50 nurses operated on for toxic goitre at our clinic all have resumed full work. As regards cardiac complications, one can almost promise subjects of paroxysmal auricular fibrillation that they will lose their attacks altogether after operation, while the majority of those with established auricular fibrillation regain normal rhythm either spontaneously or with quinidine, and in those who fail to do so the ventricular rate can nearly always be adequately controlled by digitalis. At the same time it must be emphasized that in patients with long-continued auricular fibrillation, and especially in those in whom congestive failure has resulted, the heart is irretrievably harmed to a greater or less degree, and expectation of life is consequently shortened. Generally speaking, auricular fibrillation, even paroxysmal, is an indication that surgery should have been brought to bear at an earlier stage.

X. That subtotal thyroidectomy in goitre, and especially in toxic goitre, is such a dangerous operation that it should be advised only as a last resort

That it carried a very high mortality up to twenty-five years ago is true. That to-day in unskilled and inexperienced hands the mortality rate is too high we agree. In the hands of the expert surgeon, and especially if he is a member of a trained team, it is a very different matter. In such circumstances the figures show a mortality rate for all goitres operated on of considerably less than 1%, and for toxic goitres of approximately 1%, whether they come from clinics in America, Australia, New Zealand, or this country. As this paper is written primarily for readers in this country it may interest them to know that our figures compare favourably with those of the best clinics abroad; for instance, one of us (G.K.) has operated on some 3,700 goitres—mostly toxic—with a mortality

rate of less than 1%, and another (J. E. P.) has had but one death in his last 360 cases. By the judicious use of thiouracil it is now possible, in patients with the most profound thyrotoxicosis, to achieve a degree of pre-operative improvement which was previously beyond the capacity of iodine treatment. Thus not only will stage operations, formerly sometimes necessary, usually be avoided, but the mortality rate will be almost certainly still further reduced, so that an operative death should be a very rare event. It is, however, to be remembered that the gland substance, after treatment with thiouracil, is intensely vascular and friable, with the result that operation becomes a most difficult and trying business. The vascularity can, however, be greatly reduced by discontinuing the thiouracil for two or three weeks before operation and substituting iodine—a procedure which we believe we owe to Bartels (1945) of the Lahey Clinic.

XI. That thyroid surgery requires no apprenticeship, and that the results of the occasional thyroid surgeon compare with those of the thyroid unit

Though few technical difficulties are likely to be encountered in many uncomplicated goitre operations, yet there is an important minority where such difficulties are very real, extending even the experienced thyroid surgeon to the utmost. Again, no two goitres are alike, and therefore, contrary to the usual belief, there can be no uniformity as regards the general surgical procedure. In addition the medical, in particular the cardiological, side is a matter of the greatest importance, and demands that the surgeon be associated with a physician with special qualifications. Also, in no other branch of surgery is there a greater need for an experienced anaesthetist, ether anaesthesia being, in our opinion, almost entirely contraindicated. Finally, the nursing staff not only should be experienced in dealing with the many difficulties and dangers that may arise before and after operation, but should be possessed of sympathy, consideration, and ability to inspire their charges with the greatest possible confidence. We realize that the ideal is often unattainable and that all goitres cannot be treated at goitre clinics; at the same time, it should be within the capacity of most surgeons interested in goitre surgery to organize teams on the lines we have indicated. We are convinced through our own experience that they will find it well worth their while.

Conclusion

There are, of course, many other fallacies we could discuss, but those we have dealt with are in our experience some of the most important.

In concluding we would ask a question, which is also being asked again and again by thyroid surgeons to-day in America. It is this: In face of the many dangers which beset it, ought not at any rate every nodular goitre to be removed surgically without undue delay? It was a favourite saying of Joll's that no doctor in his senses waits for a tumour of the breast to develop secondaries before he advises operation, and so why should one wait for auricular fibrillation, pressure symptoms, carcinomatous change, etc., to develop in a patient with a goitre before one advises operation?

ASTHMA IN CHILDHOOD

BY

T. N. FISHER, M.B., M.R.C.P., D.P.H.

Assistant Physician, Royal Manchester Children's Hospital;
 Honorary Physician for Children, Manchester Northern Hospital;
 Consulting Physician for Children, Warrington Infirmary

The following remarks are based on the case-notes of children suffering from asthma who have attended my out-patient clinic at the Royal Manchester Children's Hospital during the last twelve years. The main object is to draw attention to an increasing lack of balance in the approach to the problem of asthma in childhood. Too much is expected from detailed investigation of the child in hospital or asthma clinic and from the use of specific and non-specific forms of protein therapy, and not enough attention is paid to the study of the child in his normal surroundings.

This paper is concerned with those general principles that have been found helpful in the long-term treatment and management of the child and his disability—principles that are mainly directed to ensuring that the child is placed under the best possible conditions, in his natural home surroundings, for combating the disease and evading the establishment of the asthma habit. It is this aspect of the disease that I have found to be most neglected, as a result either of failure to diagnose the allergic disease in its earliest stages, or of failure to recognize the leading role that the nervous system plays in the establishment and perpetuation of the disease.

Diagnosis

The importance of early correct diagnosis cannot be over-emphasized. Of 200 children, 48% developed symptoms during infancy, either spontaneously or as a result of the mild physiological strain of teething. Here we have asthma in its purest form, uncomplicated by organic tissue change or mechanical chest deformity. Another 39% had their first attack between the ages of 2 and 6 years, often ushered in by some respiratory infection, with measles and whooping-cough well to the fore. A proportion of the children with this type of onset exhibit that inextricable blending of allergic and inflammatory disease known as the "lung-damage type" of asthma. In 87% of these children, therefore, asthma was manifest before the seventh year of life.

Chest symptoms of unexplained origin in early life should immediately arouse suspicion of allergic disease. Unfortunately diagnosis is further confounded by the ambiguous clinical picture that asthma presents at this age. Of the two closely associated allergic phenomena that are responsible for the asthma attack, turgid swelling of the mucous membrane of the smaller branches of the bronchial tree, with increased permeability and exudation of fluid, plays the dominant role in early childhood, gradually to be superseded by smooth-muscle spasm, with its characteristically more abrupt manifestation, as the child grows older. As a result of this, early allergic disease closely simulates inflammatory disease of the bronchi. Unless allergic disease is borne in mind, and the evidence for or against it carefully weighed in the light of the family history and of other symptoms presented by the child, a hasty and much too casual diagnosis of bronchitis is made, with its implication of inflammatory disease. This is a cardinal error, responsible for much subsequent confusion, anxiety, and misdirection of treatment. If muscle spasm plays an unusually predominant part the onset of the attack is more abrupt and the child is more acutely ill, with obvious respiratory distress which, in these thermolabile subjects, readily induces pyrexia. The clinical picture then bears a superficial resemblance to bronchopneumonia. To the discerning eye, however, the patient's distress is obviously due almost entirely to respiratory embarrassment; toxic symptoms are absent, recovery is rapid, often dramatically so (to the no small credit of whatever form of drug therapy has been employed), and the whole sequence of events is apt to recur, for no ascertainable reason, at intervals of a few months.

It may be that only at the age of 5 or 6 an acute spasmodic attack of the more adult type of asthma throws a sudden

vealing light on the true nature of hitherto obscure and zzzling recurrent attacks of chest trouble. By this time much rm has already been done. Inaccurately diagnosed as suffering from chronic bronchitis by medical opinion, possibly with ark hints of an underlying tuberculous disposition as a reason or the inexplicable recurrence of the attacks, accepted, pampered, and fussed over as the gifted but weak-chested member f the family circle, his first scholastic steps gravely compromised if not already abandoned in despair, the child is well on ie way to chronic invalidism if drastic steps are not taken to lter the family pattern of behaviour.

Treatment

The child victim of allergic disease has inherited an ill-balanced autonomic nervous system, which is usually part of more general nervous irritability, and an abnormal sensitivity f certain local tissue cells. This hypersensitivity, which in sthma capriciously selects the cells of the respiratory system or its chief medium of expression, probably persists, in active r latent form, throughout life.

The object of treatment must be to pursue research into the nature of the baffling laws that govern this sensitivity and, until we know more about these laws and how to control or modify them, to bring such influences to bear on the child's developing nervous system as will ensure, so far as is possible, hat his will dominates, and is not dominated by, the recalcitrant tissue cells. This aspect of the disease, with which I am mainly concerned in this paper, can most conveniently be considered under the three headings of nervous, alimentary, and respiratory.

Nervous

It is a matter of clinical observation that in the early years of life emotional excitement, especially if accompanied by some degree of physical exhaustion, is one of the two main exciting causes of the asthma attack. The other—climatic variation—is largely beyond our control. Underlying specific sensitivities may be present and we must ever be on the watch for them, but the excessive emotional reaction is the most commonly blamed detonator.

As the child grows, and his character and habits are formed, this emotional instability comes gradually more under the control of the will. The influences brought to bear on him during this formative period will help to determine whether the asthma attacks steadily decrease in number and severity, or whether this diffuse, amorphous emotional stimulus continues to elicit a response until the asthma habit is firmly established and, has become crystallized round a series of conditioned reflexes, very often largely based on suggestion. The complex psychological situations that may become superimposed on this habituation have been elaborated by Gillespie (1936) and by Kerr Clarkson (1937).

The attitude of the parents is therefore all-important in these early years. Often inherently nervous and emotional themselves, and prone to worry excessively, it is of the greatest importance to explain to them the essentially nervous basis of the disease and to define in detail their correct attitude towards the child and his disability. Previous misconceptions, particularly the fear of tuberculosis which is often at the back of their minds, must be exorcised, and their confidence and co-operation in a radically new approach to the problem must be secured. They must be enjoined to cultivate and assume an air of quiet placid confidence that the chest trouble is a childhood complaint which is not going to persist. Any exhibition of their natural anxiety in the presence of an attack must be dissembled in front of the child. He must not be made to feel that his health is the subject of constant worry and solicitude. Such undisguised concern will reflect itself in the child in various ways according to his temperament. He may exhibit a corresponding state of chronic anxiety and apprehension, or a morbid and precocious interest in his own symptoms and importance, or a vigorous self-protective negativism—all states of mind that are highly conducive to perpetuation of the asthma attacks.

The beginning of school life is an important and potentially dangerous milestone in the life of the asthma child, and a searching test of the parental ability to appreciate and cope

with the situation. The well-instructed parent will anticipate the attack, induced by the novelty and excitement, that almost inevitably follows the first adventure to school, discount it in advance with the aid of a little collaboration with the school-teacher and possibly some suitable premedication, dismiss it as lightly as possible, and return the child to school even though he may be still wheezing slightly. The over-anxious parent, on the other hand, will greet the attack with consternation and confine the child to bed or indoors for a totally unnecessary period of two weeks or more. Then an apprehensive attempt is made to resume school, with the child worried, behind in his class work, and not yet accepted into the school community. There is a repetition of the attack, and all the conditions are to hand for the establishment of a vicious circle until the mere thought of school attendance may be enough to induce a recurrence.

The second duty of the parents and those in close attendance on the child must be to cultivate all the aptitudes of patient, untiring detectives, unobtrusively noting any circumstances that are observed to lead to an attack, with a view to avoiding, so far as is possible, a repetition of such circumstances in future. But all discussion of the suspected causes of the attacks must be forbidden in the presence of the child, and, in fact, the whole subject of asthma is better avoided as a topic of family conversation, except perhaps for occasional favourable comment when there is marked improvement in symptoms. At this suggestible age children can readily become persuaded that certain foods, circumstances, or environments are likely to bring on an attack. Unwise parental comment and undisguised apprehension will increase the probability of the attack occurring. In this way expectation, which Hurst (1929) regarded as the most common psychological factor, is established at a disastrously early age. By its aid the frequency and intensity of the asthma attacks may be powerfully influenced and reinforced by the attention of the conscious mind.

Apart from this all-important parental attitude, a more stable nervous system will be encouraged by a regular daily routine of life, free from over-exciting and physically exhausting experiences, but with any suggestion of valetudinarianism rigidly excluded. Adequate hours of rest and sleep must be insisted upon, and loss of sleep due to asthma attacks must receive full compensation during the day. The hard, dry, irritating, and exceedingly intractable cough of laryngeal allergy may be a still more serious cause of loss of sleep. There can be few more distressing sights than an asthma child exhausted by loss of sleep but kept awake by this racking cough. Sedatives in large doses, which must be determined for each child, are often the only means of overcoming the local irritation.

Alimentary

The protein skin tests are undoubtedly of great theoretical interest and present a vast field for scientific inquiry. They have, however, perhaps unduly focused attention on the search for specific allergens as exciting causes of the asthma attack. When they have been employed in these children the results cannot be said to have been very helpful, and careful observation by the parents I have found to be of much greater value. Any food clearly, and on more than one occasion, proved to be at fault must be modified in some way, as with milk, or eliminated. Care must be taken, however, to see that a too zealous parent does not carry out the process of elimination to excess. In practice, specific food sensitivities appear to be inconstant and variable at this early age, and it will be found that a previously suspected food may, after an interval of a few weeks, or in a different environment, be taken with impunity. Obstinate and most dramatic examples of sensitivity to specific foods do undoubtedly occur, but, though many foods came under suspicion, none was detected in these children as the sole cause of asthma. To what extent many of the reactions to ingested and inhaled substances in later childhood and adult life have been influenced by suggestion and incautious comment by the parents in early life must be a matter of individual speculation.

Subject to the considerations outlined above, excessive dietetic rules and restrictions are better avoided. A normal balanced diet and regular meal-times are of more importance for these often exuberantly over-active mercurial children.

Respiratory

The identification of specific air-borne allergens by means of the protein skin tests presents similar practical difficulties. Dust in any form, whether the result of high winds in dry weather, spring cleaning, or any domestic or industrial activity that results in a dust-laden atmosphere, is a frequent cause of asthma attacks, many of which can be prevented by a little forethought in the home. On the other hand, the child with the lung-damage type of asthma seems to be more sensitive to damp weather, and particularly to sudden changes in atmospheric conditions.

A healthy, unobstructed upper air passage and correct breathing habits are of primary importance. Without trespassing too deeply into the realm of the ear-nose-and-throat surgeon, one may venture to express the opinion that operation should seldom be undertaken except for the elimination of infection or the relief of obstruction secondary to chronic infection. A careful distinction has, of course, to be made between the latter and the intermittent obstruction due to oedema of the pallid mucous membranes of the nasopharynx and sinuses which is a feature of allergic disease.

It is certainly most unwise to make any optimistic promises of permanent relief from the asthma symptoms as a result of any operative procedure. Fifty-seven children under my care have had their tonsils and adenoids removed. The results, noted at least six months after operation, were: in 12 marked improvement was reported; in 36 no change in the incidence or severity of the attacks; in 6 the asthma was said to have been worse; and in 3 the operation was blamed for the onset of the disease.

Having ensured a free and unobstructed upper air passage, breathing exercises, based on the suggestions contained in the handbook published by the Asthma Research Council (1944), undoubtedly supply one of the most beneficial forms of therapy in this disease.

The child suffering from the lung-damage type of asthma presents a particularly difficult problem. Prevention, by treating those twin menaces to the organic structure of the lung; measles and whooping-cough, with even greater respect than usual in a potential asthma subject, and insisting upon protracted convalescence until the symptoms and physical signs of any respiratory infection in his early years have cleared completely, must be our first aim. When this type of asthma is already established it demands most careful investigation of the whole respiratory tract, with the co-operation of the bacteriologist, radiologist, and ear-nose-and-throat surgeon, in addition to the general measures of treatment.

Conclusion

A steady tendency to diminution in the severity of the attacks and cessation of symptoms for increasingly long periods as the child grows older was noted in the majority of these children. Those who develop symptoms in infancy and present the most uncomplicated form of the disease yield the most promising results, provided the diagnosis is prompt and the parents are intelligent and co-operative. Those suffering from the lung-damage type of the disease did not show the same promising progress. A follow-up has not been attempted. To be of any value a survey in ten or twenty years' time, noting the effects of adolescence and, in females, the events of the reproductive cycle, would be the only satisfactory way of pursuing the inquiry.

As has been emphasized, prognosis is vastly influenced by the character of the parents and the home circumstances. A temporary change of surroundings, various combinations of drugs, or specific or non-specific protein injection therapy may bring about an improvement of variable duration, often a most satisfactory and sustained remission. It may be added that the incidence of an acute illness, an operation, or indeed any abrupt change in the normal routine of life may bring about the same happy though often temporary alleviation. One or other of the former methods will often help to steer the child through a particularly severe phase of the disease, and a remission brought about by one of the latter events should be exploited to the full by insisting on prolonged convalescence. A subsequent relapse will, however, cause serious loss of confidence in

both child and parent if the importance of taking the long-term view is not constantly inculcated into all concerned.

No rapid results, but a steady improvement in the later years of childhood, can be promised, and must be tacitly assumed by all as an integral part in the treatment and management of the disease.

PERFORATION OF THE ILEUM IN
ENTERIC FEVER

NOTES ON 22 CONSECUTIVE CASES

BY

G. E. DUNKERLEY, M.B., B.S.

Few diagnostic problems are more urgent and yet more difficult to solve than those encountered in perforated typhoid ulcer. A recent analysis of the cases which have occurred during the last eleven years at the Kolar Gold Field Hospital, South India, has confirmed the belief, based on clinical experience, that the picture and subsequent course of perforated typhoid ulcer in this locality differ in certain respects from the accounts generally presented in textbooks. The information obtained from the records of 22 ileal perforations treated in this hospital between 1935 and 1945 is thought to be interesting enough to form the subject of a short paper.

Textbook Description

Perforation of the ileum occurs in a little under 5% of all cases and causes 30% of all deaths in enteric fever. It is said to be especially common in cases characterized by diarrhoea, meteorism, or haemorrhage from the bowel, and is most frequent towards the end of the third week, but may occur at any time after the second week. Diagnosis is difficult, for few of the classical signs and symptoms of perforation occur in the late stages of fever, when toxæmia is severe and the patient may be almost moribund. Authorities state that the first sign is often a rigor, sharp or sudden pain in the right iliac fossa or lower abdomen, with unusual tenderness and rigidity. One source of information suggests that collapse is unusual, but another gives sudden collapse as a common initial symptom. The temperature may fall temporarily or may be unaffected, while the pulse rises. After perforation a deceptive improvement may occur. The onset is so insidious in some cases that at necropsy unsuspected general peritonitis is found: If the affected loop lies in the pelvis, frequent and painful micturition or rectal tenesmus, and tenderness on digital examination, may be prominent symptoms. The pain in the abdomen is severe and persistent, increasing distension appears with early rigidity, and liver dullness may be obliterated. Opinions concur that an early polymorphonuclear leucocytosis generally accompanies the perforation but is an inconstant sign, while general leucocytosis does not appear early enough to be of value. The perforation generally lies within 12 in. (30 cm.) of the caecum, but may be elsewhere. Two or more perforations occur in 10% of cases. The mortality is admitted to vary from 75 to 95%, while perforation in ambulant cases is thought to be particularly high.

Incidence in Present Series

The series of cases to be described varies in some respects from the above clinical picture. During the eleven years 1935-45, 1,077 cases of enteric fever were treated in the Kolar Gold Field Hospital, and a total of 11 perforations occurred in patients under treatment—an incidence of 1%. Of these cases 10 were in hospital at the time of perforation and 1 was in bed at home. A further 11 perforations took place among patients with ambulant enteric fever, and these already had perforation with general peritonitis on admission. Twenty-two cases of perforated typhoid ulcer have thus been operated upon in this hospital in the period under review. Though the

incidence of perforation in ambulant cases cannot be estimated, the occurrence of the same number of perforations in ambulant as in non-ambulant cases is evidence of the prevalence of such mild enteric fever that the sufferers do not seek medical attention.

The hospital treats Indian mining employees (25,000), and Anglo-Indian and European employees and their families (3,000). The employees are almost all male, their ages varying from 15 to 65 years. All 22 cases were in males; the eldest was 50 and the youngest 6, the average age being 28, which is probably a little lower than the average age of employees. Seven were employed on surface work, and the remainder were underground workers. Two children aged 6 and 13 years are included. The younger was a schoolboy, a non-ambulant patient who spent eight days in bed at home before perforation; the elder was ambulant; both recovered.

Trauma.—One patient received a contusion of the abdominal wall while at work on the day of admission. It was conceded that the accident was a possible factor in causation of his perforation.

Preliminary Course

The length of history before perforation in non-ambulant cases, including illness before admission, was 9, 5, 8, 13, 11, 9, 12, 12, 8, and 18 days; average, 11 days. In two cases the length of history was not obtainable from the records. In ambulant cases symptoms of various kinds were experienced for 0, 3, 0, 15, 2, 3, 7 days before perforation. The average in these cases was 4 days, but in four cases no mention of this detail was recorded. Haemorrhage did not occur in any case prior to perforation. Diarrhoea was a preliminary feature in only one case of the series, and the occurrence of meteorism was not a prominent sign in any case before peritonitis.

Symptoms and Signs

Symptoms at Onset.—(a) Pain: In every case in which the symptoms at onset were recorded abdominal pain occurred. It was described as of sudden or shock-like onset in 4 cases, and in 6 it was severe when it began. In 4 the pain was chiefly in the lower abdomen; in the remainder it was general or referred to the vicinity of the umbilicus. (b) Irritation of Pelvic Viscera: Pain was the first symptom in all but one case, in which a desire to micturate preceded it. One other case had urinary symptoms or pain on micturition soon after the onset of abdominal pain. Two patients had symptoms of rectal irritation in the form of several loose motions after abdominal pain had started. In one of these a little blood was present in the faeces. (c) Vomiting: This was present at the onset in 5 cases, and had occurred a day or two before perforation in one other case (ambulant). Only two patients vomited more than once; one of whom vomited twice, another five times. (d) Rigor: Two patients had a rigor at or soon after perforation. (e) Temperature and Pulse: The average temperature and pulse rate on admission in ambulant cases were 100.2° F. (37.9° C.) and 110, with extremes of temperature of 97° and 102.6° F. (36.1° and 39.2° C.), and of pulse rate of 80 and 152. The patient whose temperature was 97° was the only one in the series who was afebrile on diagnosis. In the non-ambulant group the average temperature and pulse rate on diagnosis were 102° F. (38.9° C.) and 109, with extremes of 99.6° and 103.6° F. (37.55° and 39.8° C.) and of 88 and 130. (f) General Conditions: In 13 cases this was recorded or could be deduced from the records as follows:

General Condition	No. of Cases	Result	
		Recovered	Died
Good	1	1	0
Fair	7	3	4
Poor	4	0	4
Collapsed	1	1	0

Later Symptoms and Signs.—Careful notes of the degree of pain, tenderness, and rigidity at the time of examination were present in the records of 16 cases. (a) Pain: Severe in 8, and of moderate intensity in 8. It was general or around the umbilicus in all except one, in which it was worst in the iliac fossae. (b) Rigidity: This was severe in 4, moderate in 8,

mild in 2, and absent in 2. It was greater in the lower abdomen in 3. (c) Tenderness: This symptom was severe in 5, moderate in 8, and mild in 3. It was greater in the right iliac fossa in 2, in the left iliac fossa in 1, in the lower abdomen in 2, and in the epigastrium in only 1 case. (d) Liver dullness was mentioned in only 5 case notes; it was present in 2, diminished in 2, and absent in 1. In 1 case shifting dullness was detected.

Blood Examination

Early total white blood cell counts were recorded in 5 cases, with a maximum of 12,000 leucocytes per c.mm., a minimum of 2,400, and an average of 7,500. The differential count was recorded in 4 cases as follows:

	Maximum %	Minimum %	Average %
Polymorphs	80	65	76
Lymphocytes	30	15	21
Mononuclears	5	2	3
Eosinophils	0	0	0

Blood was taken for a Widal test on the day of operation or within the next two or three days in 13 cases, and proved negative in 5. Haemagglutinins were employed, as the native community among which these cases occurred is not protected by T.A.B. inoculation. The results are:

Dilution:	1/50	1/100	1/125	1/150	1/250
No. of cases ..	2	1	2	1	2

Agglutination was highest against *B. typhosus* antigen in all but one case, in which *B. paratyphosus A* was agglutinated 1/50.

Surgical Procedure

In non-ambulant cases the time interval between perforation and operation averaged 11 hours, with extremes of 2 and 20 hours. In ambulant cases the exact period could be ascertained only in 4, with extremes of 7 and 26 hours, and an average of 13 hours. Among those with accurate records of time intervals, of 6 cases repaired within 12 hours 4 recovered; of 3 repaired from 12 to 24 hours after onset 2 recovered; and of 2 operated on from 24 to 36 hours after operation 1 recovered.

In all cases anaesthesia was induced either by nitrous oxide and oxygen or by chloroform-ether mixture 1:12, and was followed by open ether. A right paramedian incision was used in every case. When the correct diagnosis was established before operation a small low incision was made—low for convenience of access, and small to minimize the risks or extent of subsequent ventral hernia. The latter complication was a distinct hazard in cases of typhoid perforation, as many wounds in those who recovered became infected. The perforation was repaired with interrupted sutures through all coats transversely and buried by a continuous seromuscular stitch. Omentum was sewn over the repaired site. Later cases had 10 g. of sterile sulphanilamide powder intraperitoneally without any apparent influence on mortality. All were drained by separate suprapubic stab wound and rubber tube to the pelvis. The site of perforation was recorded in the notes of 13 cases. In 8 the following estimated distances from the ileo-caecal junction were observed: 12, 6, 9, 18, 3, 12, 15, 10 in. (30, 15, 22.5, 45, 7.5, 30, 37.5, 25 cm.). The average distance between a perforation and the ileo-caecal valve was thus 11 in. (27.5 cm.). In the 5 remaining cases the perforations were described as being in the lower ileum.

Post-operative Course and Mortality

Wound infection was a troublesome sequel in 8 cases, and was classified as severe in 5, moderate in 1, and mild in 3. One case had no wound infection, and most of the remainder died before definite evidence on this point was obtainable. Among those who died the period of survival after operation varied from 2 hours to 6 weeks; average, 7 days. Excluding the individual who survived 6 weeks the average period of survival was 4 days. Including those who died the average duration of fever after operation was 12 days; excluding deaths it was 18 days.

There were 5 deaths in the 11 ambulant cases, and 7 deaths in non-ambulant cases. The total mortality was therefore 55%; that in ambulant cases was 45%, and in non-ambulant cases 64%. The 7 deaths in non-ambulant cases represent the mortality from ileal perforation among the 84 deaths in 1,077 cases of enteric fever—i.e., 8% of all deaths. Mortality from all causes in enteric fever was 8%, and from perforation 0.7%.

Necropsy was not performed on patients dying from enteric fever. As it is possible that some died with unsuspected ileal perforation and general peritonitis the figure of 1% for the incidence of perforation in 1,077 cases may be somewhat low.

Table showing Mortality from Enteric Fever during the Period 1935-45

Year	All Cases Treated in Hospital			Cases with Perforation (Ambulant and Non-ambulant)	
	No.	Deaths	Mortality %	No.	Deaths
1935	21	2	10	1	—
1936	20	2	10	1	1
1937	59	5	8	2	1

1944	142	9	6	5	3
1945	79	6	8	—	—
Total ..	1,077	84	9	22	12

Discussion

Haemorrhage from the bowel did not occur in any case before perforation; persistent diarrhoea occurred only once, and meteorism severe enough to find special mention in the notes not at all. Rigor was an initial sign in only two cases. Four of the series conformed to the recognized description of irritation of the pelvic viscera by proximity of the perforated loop; dysuria and rectal tenesmus were present. Pain was the predominant initial symptom, and it was usually general or situated around the umbilicus. In only a small proportion was the first pain described as low, and it was never referred to the right iliac fossa.

When a clearer clinical picture had had time to develop, the symptoms and signs remained chiefly general, and reference to the iliac fossae was not the rule. Rigidity was greater in the lower abdomen in only 3 cases; and tenderness was greater in the right iliac fossa in 2, in the left iliac fossa in 1, in the lower abdomen in 2, and in the epigastrium in 1. It is clear that localization of symptoms and signs to the right iliac fossa in these cases was unusual. This is not unexpected. If the perforation occurred at the ileo-caecal junction pain in the right iliac fossa might logically be expected, but as the perforation was an average of 11 in. (27.5 cm.) from the junction—that is, about as far away as the average width of the abdomen—it is obvious that localized signs, if any, may appear anywhere in the abdomen. Some patients had no rigidity, slight pain, and mild tenderness—symptoms associated with some cases of enteric fever without perforation.

Fall of temperature to below normal was present in only one case—an ambulant one. A relative fall doubtless occurred in some cases, but was certainly not great, as the average temperature when diagnosis was made was 101° F. (38.3° C.). Increase in pulse rate takes place at the onset, and, as in other forms of peritonitis, the rate increases progressively unless a response is obtained by specific treatment. It seems that the general condition at the time of diagnosis is a useful prognostic sign.

The average time interval between perforation and operation was 11 hours. This long period is evidence that the onset was dissimilar to the catastrophic nature of perforation of a gastric or duodenal ulcer. In several cases the onset was particularly insidious; the patient was examined either as the result of some mild deterioration in condition noticed by the nurse, or during the routine daily round, and found to have signs of general peritonitis. Questioning did not reveal any outstanding symptoms indicating beyond doubt the actual time

of perforation. Thus in four cases the interval between perforation and operation was doubtful.

The figures given of recovery rate in relation to time laps do not illustrate the advantage of early operation, and are to be disregarded as not representative of the whole series. Blood counts were performed shortly after clinical examination has suggested the presence of peritonitis: although the total leucocyte count was within normal limits, the polymorphonuclear leucocytosis is considered to be of diagnostic value.

The early occurrence of perforation is noteworthy. Excluding ambulant cases (date of onset unknown), the average interval between commencement of illness and perforation was 11 days. This is widely at variance with the usual belief that the commonest time for perforation is the end of the third week. The fact that perforations do occur at this early period is substantiated by the average duration of fever after operation. Excluding deaths it was 18 days; even including deaths (average survival period 7 days) it was 12 days.

In the whole series of 1,077 cases of enteric fever 1% developed perforation of the ileum, in contrast with the usual expectation of 5%. This complication accounted for 8% of the total deaths, against the usual total of 30%. Perforation is five times less frequent than is mentioned in textbooks, and peritonitis as a cause of death four times less frequent; subject to the proviso that this conclusion has not been verified post mortem.

The mortality from perforation in this series is low when compared with the usual figures published, being 55% for the whole series and even lower in ambulant cases—namely, 45%. This is at variance with the impression that perforation of a typhoid ulcer in an ambulant patient is of particularly grave prognosis, and is no doubt associated with the absence of severe toxæmia preceding perforation in the local type of case.

To sum up, the most striking features emerging are:

1. Low mortality rate in a long series of cases of enteric fever
2. Low incidence of perforation of the ileum.
3. Low mortality among those which did perforate.
4. The early period in the disease at which perforation took place.
5. Other variations from normal of subsidiary importance are the infrequency of diarrhoea, haemorrhage, or meteorism before perforation, and infrequency of rigors at onset.

The explanation of the first three factors must be either that enteric fever contracted in this part of Southern India is of a relatively benign variety, or that the type of treatment the patients received was attended with more success than usual. It is true that diarrhoea, haemorrhage, and meteorism—signs of a severe attack—were infrequent. Moreover, in my experience the recurrence rate is much less than the usually accepted 10%. On the other hand, it is to be expected that perforation would occur later in the course in milder cases, and an adequate explanation of its early appearance cannot be offered.

The treatment of enteric fever has been symptomatic, but a radical departure from common practice has been made in the abandonment of a liquid diet. Perforation of the intestine in enteric fever almost always takes place in the last 3 ft. (91.5 cm.) of the ileum, usually in the last foot (30.5 cm.), and ordinarily digestible food has been reduced to the physical characteristics of a liquid when it reaches this situation. It therefore appears to be not only unobjectionable but probably beneficial to permit patients with enteric fever to indulge their appetite for suitable solid food without restriction.

No attempt has been made to enforce any particular diet, but the usual dietary habits of the workmen have been followed according to their desires. In health the workman partakes of coffee, bread, or congee (cereal boiled to a paste in water) in the early morning, and large meals of curry (highly flavoured and coloured spiced meat) and rice at midday and in the early evening. When sick the patient resorts to milk, congee, coffee, and bread. On admission to hospital cases of enteric fever are at first given a diet of milk, coffee, congee, and bread-and-butter. When appetite improves or the patient can comfortably take extras, eggs, milk puddings, soup, fruit, fish, and mince are added, and if the patient desires it he is given curry and rice once or twice a day according to his requirements. Patients

are always eager to take a full diet as soon as they are able, and this attitude is encouraged. Constipation is the rule, and diarrhoea is uncommon. Purgatives are never given; enemas only infrequently.

It may be that enteric fever in Kolar is comparatively mild, but it is thought that the dietary treatment has perhaps influenced prognosis for the better. At any rate, the patients have only enteric fever to contend with—the additional factor of semi-starvation has been eliminated. There is room for argument as to whether this form of diet has had a beneficial influence; but mortality statistics suggest that it has not had a deleterious effect.

Summary.

A series of 22 consecutive cases of perforation of the ileum in enteric fever is described.

Perforation occurred unusually early—in the middle of the second week.

In 1,077 cases of enteric fever in hospital 11 perforations were detected. An equal number were met with in ambulant patients, indicating the existence of widespread ambulant enteric fever in this community.

The low mortality from enteric fever, the low incidence of perforation, and the comparatively low mortality from this complication are discussed with reference to the virulence of the infection met with and the possible effect of the treatment given.

I have much pleasure in expressing my thanks to Dr. W. B. Roantree, Chief Medical Officer, Kolar Gold Field, for his invaluable help in the preparation of this article, and I acknowledge my indebtedness to him and to Dr. J. M. Daly for allowing me to use the records of the cases which they treated.

AMOEBIASIS IN ITALY

BY

GRAHAM W. HAYWARD, M.D., F.R.C.P.

Assistant Physician, St. Bartholomew's Hospital; late Lieut.-Col., N.Z.M.C., Officer in Charge, Medical Division of a New Zealand General Hospital, C.M.F.

Recent accounts of amoebiasis occurring in India and Burma (Leishman and Kelsall, 1944; Payne, 1945) have described the difficulties of treatment and the high relapse rate, while treatment in the United Kingdom of men invalided from these theatres has again given poor results (Lamb and Royston, 1945; Bomford, 1944). The clinical picture of amoebiasis in Italy is different. Here the more obvious dysenteric symptoms are usually absent, and the chief difficulty is in the diagnosis of the chronic or the latent case. Once diagnosed the response to treatment is good and the relapse rate low. The present paper gives an account of the disease as it has been encountered in a New Zealand General Hospital, C.M.F., during the past year.

During the period July, 1944, to June, 1945, 4,601 patients were admitted to the Medical Division, and the relative frequency of "tropical" diseases is shown in Table I. It will be seen that amoebiasis accounts for over half the admissions in the diarrhoea-dysentery group and was 2½ times as common as malaria. This article is based on the 258 cases of amoebiasis seen during this period.

TABLE I.—Total Admissions July, 1944, to June, 1945 (4,601)

Infective hepatitis ..	2,016	Dysentery, bacillary	104
Amoebiasis, intestinal ..	252	Malaria ..	103
Amoebiasis, acute hepatic ..	6	Other diseases ..	2,006
Diarrhoea ..	109		

The duration of symptoms before admission varied from a few days to 18 months, with an average of 3–4 months. Of the 252 cases of intestinal amoebiasis, 82 were admitted primarily for other diseases, such as infective hepatitis, peptic ulcer, ascariasis, or anxiety neurosis, and the disease was in a latent or a chronic stage.

Symptoms

Diarrhoea.—A history of diarrhoea was given by 204 cases (81%). Of these, 70 were admitted with an acute attack, and 134 gave a history of mild recurrent attacks lasting 1 to 3 days and subsiding readily with R.A.P. (Regional Aid Post)

treatment. True dysenteric symptoms of blood and mucus in the stools were seen in only 28 cases, and of these 16 had an associated bacillary infection. Forty-eight cases (19%) had had no attacks of diarrhoea since coming overseas.

Pain.—Complaints of abdominal pain were made by 106 (42%) patients. This was of three main types: (a) Recurrent attacks of aching, lower abdominal pain, particularly situated in the right iliac fossa and often associated with looseness of the bowels. (b) Epigastric pain or discomfort, related to food and resembling the pain of a peptic ulcer. Associated with this type of pain were often dyspeptic symptoms—anorexia, flatulence and nausea—and many patients were admitted with a tentative diagnosis of peptic ulcer or functional dyspepsia. Four cases had a radiologically proved duodenal ulcer in association with amoebiasis. (c) Aching pain in the right subcostal region, worse on lying on the right side, and often associated with a flatulent type of dyspepsia.

General Symptoms.—Vague general symptoms of lassitude, malaise, anorexia, and slight loss of weight were common, and in these cases a history of diarrhoea was usually obtained only by direct questioning. Weight loss was never severe, and no cases showed any marked evidence of toxæmia or debility.

Physical Examination

The most valuable physical sign in the diagnosis of intestinal amoebiasis is tenderness or thickening in the region of the caecum, and this was present in 63% of cases. There was often tenderness over both the ascending and the descending colon. Liver enlargement was found in 103 cases (41%), of which 37 had a coexisting infective hepatitis. This group will be discussed later. No help in the diagnosis of the uncomplicated case of amoebic dysentery was obtained from either the blood count or the sedimentation rate.

Sigmoidoscopy

This is a most valuable aid to diagnosis, and its routine use in all cases with a history of chronic diarrhoea or of vague dyspeptic symptoms occurring in a country where amoebiasis is prevalent would prevent many cases being missed. In the present series of 252 cases with positive stools, the majority of which were of the mild chronic type, 70% showed abnormal findings on sigmoidoscopy. This figure would have been higher had it been realized earlier that the type and extent of the ulceration seen in Syria and North Africa were uncommon in Italy and that the changes here were much less marked but none the less characteristic. The following changes have been observed:

(a) *Small superficial ulcers*, about 1–2 mm. in diameter, but seen on the valves and very easy to miss because of the frequent absence of a surrounding area of hyperæmia. In most cases, ulcers, if present, will be found on the lower four inches (10 cm.) of the bowel.

(b) *Pitting of the Mucosa*.—The treated case of amoebiasis may show pitting of the mucosa at the site of ulceration for several weeks afterwards. This appearance occurring in an untreated case, giving a history of intermittent diarrhoea (often admitted to hospital when the bowels have returned to normal), is highly suggestive of amoebiasis, and stool examination after purgation will show the *Entamoeba histolytica* in nearly all of these cases.

(c) *Granular proctitis* or patchy areas of granularity, often extending upwards into the colon, associated with excess of mucus on the bowel wall and often scattered submucosal haemorrhages. These changes are non-specific, but are often associated with an amoebic infection of the bowel. Amoebae may sometimes be found in mucosal scrapings from the ulcerated and pitted areas, but in the latent or chronic cases the percentage of positive findings obtained has not been high.

Stool Examination

The most certain method of diagnosing amoebiasis is the demonstration of the typical vegetative forms of *E. histolytica* in the stools. In the rare acute type of case passing blood and mucus in the stools, the finding of the entamoeba is a matter of no great difficulty if a fresh warm stool is examined. In the mild chronic type of case, which provided 72% of the total, considerable difficulty has been found in demonstrating amoebae, even when on clinical and sigmoidoscopic examination the diagnosis seemed certain. The usually advocated policy of examining six daily stools produced negative results in most

cases, and even the daily use of salts to provide a loose stool gave only a slightly higher proportion of positive findings. This difficulty has been overcome by producing frequent watery stools with the aid of calomel and magnesium sulphate, and sending up to the laboratory all stools passed on the day of the test. In this way a positive result can be obtained in one day in nearly all cases. Calomel, 5 gr. (0.32 g.), is given at night, and magnesium sulphate at 7 and 9 o'clock next morning. In the last 100 cases diagnosed in this way a positive result was obtained in the first stool in 24% of cases, the second stool in 15%, the third stool in 25%, and the fourth, fifth, and sixth stools in 8% each. Rarely, eight to ten stools would have to be examined before a positive result was obtained, but the average number was 3.5. The common sequence is for the first one or two stools to be negative; then, as they become watery and contain mucus, amoebae are found which at first may be atypical and only sluggishly motile. Subsequent stools in this case will almost invariably show actively motile amoebae containing red blood cells which are in every way typical of the *E. histolytica*. The exudate in the stool was occasionally "indefinite," but usually there was no exudate. An unusual finding in this series was the infrequency with which amoebic cysts were found in the stools—5% of the cases only. (Concentration methods were not used as a routine.)

The occurrence of amoebic ulceration of the colon with vegetative forms of *E. histolytica* in the stools in a patient entirely free from symptoms is not unknown. Several instances were encountered when undertaking a routine examination of stools from 23 cooks in a unit in which there was a continued mild incidence of amoebiasis. In six cases trophozoites of *E. histolytica* were found, and in one other cysts of *E. histolytica*. All seven men felt in good health and had not reported sick, although on close questioning three admitted to having had occasional mild attacks of diarrhoea during the previous three months. In four of the seven cases sigmoidoscopy revealed active amoebic ulceration.

X-ray Examination

The barium radiograph is in most cases of little value in diagnosing intestinal amoebiasis. In a few cases where the history has suggested a peptic ulcer, a barium follow-through has shown localized spasm of the caecum or colon, and subsequent stool examination has been positive for *E. histolytica*. The radiological changes in hepatic abscess and acute amoebic hepatitis are well known and need not be further discussed here. There is, however, a small group of cases which give a history of recurrent mild diarrhoea associated with malaise, lassitude, aching pain in the right subcostal region, and in which screening of the diaphragm shows a localized doming of the right half of the diaphragm in the postero-medial aspect, with restricted movement. These cases have been afebrile, with normal blood counts, and stool examination has usually been negative for amoebae. The marked subjective improvement following emetine treatment, coinciding with a diminution in size of the liver bulge, makes the clinical diagnosis of chronic amoebic hepatitis probably a correct one. These cases have not been included in the present series as some doubt exists about the correctness of the diagnosis.

Treatment

The depressing results from standard courses of treatment reported from India and Burma have not been experienced in Italy, and it is obvious that there the disease runs a much milder course and responds more readily to treatment. During the early part of this year the standard M.E.F. (Middle East Forces) treatment was used (emetine, 1 gr. (65 mg.) daily, with quinoxyl 2½% enemas for 10 days, carbarsone 0.25 g. twice daily for 8 days, followed by emetine bismuth iodide, 3 gr. (0.2 g.) for 12 days), and latterly the C.M.F. (Central Mediterranean Force) course (emetine, 1 gr. daily for 3 days, emetine bismuth iodide 3 gr., concurrently with quinoxyl 2½% retention enemas for 10 to 12 days, followed by carbarsone, 0.25 g. twice daily for 8 days), strict attention being paid to the technique of giving the quinoxyl (Manson-Bahr, 1944). All cases with liver enlargement or in which there was any suspicion of amoebic hepatitis were given 10 gr. (0.65 g.) of emetine during their initial course of treatment and a further course of 6–10 gr. (0.4–0.65 g.) after

three weeks at the convalescent depot. The immediate result have been good, and only two cases still had positive stool when examined three weeks after the conclusion of treatment. A complete follow-up of all cases has not been possible, but as nearly all the cases occurred in New Zealand troops and all long-term cases or cases for evacuation from this theatre are transferred to this hospital, it is possible to give some idea of the relapse rate. To date 9 cases are known to have relapsed. 226 men have returned to full duties, 7 have been down-graded for base duties, and 19 have been graded unfit for further service overseas, chiefly because of persistent hepatomegaly or the presence of some associated condition such as coronary artery disease or duodenal ulcer.

Three of the relapsed cases with persistent diarrhoea, extensive ulceration of the colon, and trophozoites of *E. histolytica* in the stools have been treated with a 5-day course of sulphasuxidine (80 g.) and penicillin (1,200,000 units) before being given a second course of emetine bismuth iodide and quinoxyl (Hargreaves, 1945). The immediate results have been good, ulceration of the bowel healing and amoebae disappearing from the stools; but a further follow-up over a longer period will be necessary before they can be said to be cured.

Discussion

The difference between this series of cases and those reported from other theatres of war is obvious. In Italy the disease is for long periods mild or latent, and characterized either by recurrent attacks of diarrhoea or by persistent malaise with vague abdominal symptoms. Dysenteric symptoms are unusual (28 cases), and then often associated with a bacillary infection, while, in 82 of the cases the primary admission to hospital was for some other disease. There is no definite evidence that an avirulent strain of *E. histolytica* exists, although it might be doubted if the amoeba was the cause of the vague general symptoms predominating in so many of these cases. The presence of ulceration as seen with the sigmoidoscope and the response to specific treatment, with subjective improvement much more pronounced than could be accounted for by a similar period of rest in bed and an adequate diet, leave little doubt that the amoebic infection is the cause of the symptoms and that the amoeba is not a harmless parasite in the bowel. Bearing in mind the possibility that some of these patients will, if untreated, develop signs of amoebic hepatitis or hepatic abscess after the war, the demonstration of *E. histolytica* in the stools should lead to the institution of a full course of anti-amoebic treatment. Although doubt exists whether an emetine-resistant strain of amoeba may be reproduced by repeated inadequate courses of treatment, there is little doubt that the relapse rate under these conditions will be high, and so during the first course of treatment every effort should be made to eradicate the infection.

The diagnosis of clinical intestinal amoebiasis is as unsatisfactory as that of clinical malaria, and the empirical use of emetine or emetine bismuth iodide in all cases of chronic diarrhoea is rightly condemned. Especially in the type of disease described in Italy with such vague general symptoms it is important to make an exact diagnosis by demonstrating the amoeba before starting a long unpleasant course of treatment. With the aid of the method of examining succeeding stools following a single purge as described in this paper and used in many hospitals in the C.M.F., it should be possible to make an exact diagnosis in nearly all cases of intestinal amoebiasis. Characteristic lesions seen with the sigmoidoscope should lead to a search for *E. histolytica* either by means of mucosal scrapings or by examination of the stools after purgation.

The diagnosis of amoebic hepatitis is nearly always a matter of considerable difficulty, and little help is obtained from stool examination, which gives positive results in only about 45% of cases (Manson-Bahr, 1940). The six cases of acute amoebic hepatitis treated all showed leucocytosis, tender enlargement of the liver, and fullness of the right lower chest, and responded to emetine injections. The diagnosis of chronic amoebic hepatitis usually has to be made on clinical grounds only. The finding of an enlarged tender liver in a patient giving a previous history of recurrent attacks of diarrhoea, with negative results from stool examination and sigmoidoscopy, is not

uncommon in this theatre. If marked subjective improvement and diminution in size of the liver follow the administration of a course of emetine injections the diagnosis of chronic amoebic hepatitis is probably the correct one. Frequently, however, the liver remains unchanged in size and the diagnosis is in doubt. Because of this difficulty it was decided to follow up the 103 cases with liver enlargement occurring in this series of 252 cases with positive stools. Thirty-seven of these were originally admitted with infective hepatitis, and the persistence of hepatomegaly long after the jaundice had disappeared led to a search for possible contributory causes and the discovery of a latent amoebiasis. All cases were afebrile, with a normal white count and sedimentation rate, and their failure to respond to emetine treatment made the diagnosis of amoebic hepatitis unlikely. A follow-up of this group of cases over a period of six months showed that no case developed an amoebic abscess and that in all but seven cases the liver had returned to normal size in three months without further anti-amoebic treatment. The course of these cases has been exactly comparable to that of similar cases of infective hepatitis with residual hepatomegaly in which no evidence of amoebiasis was found and no emetine was given. One patient with combined infective hepatitis and amoebic dysentery with residual hepatomegaly died of intercurrent disease six weeks after he had completed his anti-amoebic treatment; histological examination of the liver showed no evidence of amoebic hepatitis and nothing to suggest that he had had a recent attack of infective hepatitis. Considering the large number (2,016) of cases of infective hepatitis admitted and the probable high carrier rate in troops exposed to amoebic infection, it is suggested that the association of these two diseases is accidental, and that the amoebic infection played no part in causing the persistence of the liver enlargement.

The cause of liver enlargement—usually two or three finger-breadths—in the remaining 66 patients who gave no history of preceding infective hepatitis remains uncertain. In addition to the vague general symptoms and mild recurrent diarrhoea typical of chronic amoebiasis, a history of aching pain in the right subcostal region, worse on lying on the right side, and a sense of fullness in the right lower chest, was often obtained. All of these cases were afebrile, with a normal white count and sedimentation rate. Aspiration of the liver gave negative results in all cases in which it was performed. In one-half of these cases the liver returned to normal size after a course of emetine injections, and the aching pain and sense of fullness in the right lower chest disappeared. In these cases the diagnosis of chronic amoebic hepatitis in association with intestinal amoebiasis seems justified. Diminution in liver size after emetine treatment in the remaining patients was no more than could be ascribed to a long period of rest in bed with a bland high-carbohydrate high-protein diet, and at the conclusion of treatment the liver remained slightly enlarged, firm, and often tender. These cases with persisting liver enlargement were down-graded, and were observed at base for a period of three to six months. At the end of this time all were in good health; none had suffered a relapse of amoebiasis or showed signs of liver abscess, but the liver was still undiminished in size. In view of the failure of the therapeutic test a diagnosis of chronic amoebic hepatitis seemed unjustified, and other possible causes were looked for. During the autumn of 1944, when many of these cases of amoebiasis occurred, there was a high incidence of infective hepatitis in the New Zealand Expeditionary Force, and it is known that many cases of "hepatitis without jaundice" occurred in which the prodromal febrile illness with digestive symptoms was not followed by the development of jaundice, although the liver became enlarged and tender. These cases ran a mild course and the liver returned to normal size in two to three weeks, so that it is unreasonable to ascribe the persistent liver enlargement in amoebic dysentery to a previous unrecognized attack of infective hepatitis. It is more probable that it is a chronic non-specific hepatitis related to the hepatitis sometimes found in association with chronic non-specific dysentery or in chronic diarrhoea. Whether it represents an early cirrhosis is a problem which might be solved by liver biopsy, and further observation of these patients over a period of years is indicated.

Clinically, chronic amoebic hepatitis and chronic non-specific hepatitis found in association with intestinal amoebiasis are

usually indistinguishable. Thickening of the skin and subcutaneous tissues over the right lower chest wall without actual pitting oedema is often found in chronic amoebic hepatitis, and localized tender spots in the intercostal spaces over the liver would also point to this diagnosis. The distinction is largely academic; from a practical point of view it is important that any case of intestinal amoebiasis in which liver enlargement is found should receive a full course of emetine injections, and reliance in treatment should not be placed solely on drugs such as emetine bismuth iodide, quinoxyl, and carbarsone, which act only on the amoebae in the bowel wall.

The occurrence of vague abdominal symptoms in a soldier returning from an overseas theatre where amoebiasis is known to be prevalent should lead to the diagnosis of chronic amoebiasis being considered. These symptoms may easily be labelled functional in origin, as indeed they often are. The question of amoebiasis can be quickly settled by sigmoidoscopy and examination of successive stools after a brisk purgative has been given. If sigmoidoscopy shows lesions in the rectum and colon, and vegetative forms of *E. histolytica* are found in the stools, a full course of anti-amoebic treatment should be given. There is some doubt whether it is justifiable to institute a long and unpleasant course of treatment in amoebic "carriers," where the only positive finding is the presence of cysts of *E. histolytica* in the stools. As it is impossible to forecast which of these patients will, at some later date, develop amoebic hepatitis or liver abscess, it has been our practice to attempt to eradicate the infection with emetine bismuth iodide, quinoxyl, and carbarsone.

Summary

An account has been given of the cases of amoebiasis treated in a New Zealand General Hospital in Italy during the period July, 1944, to June, 1945.

True dysenteric symptoms were rare and were often associated with a bacillary infection. The disease was usually of the latent or chronic type, with recurrent mild attacks of diarrhoea and general symptoms of malaise, dyspepsia, and slight loss of weight predominating.

Tenderness and thickening in the region of the caecum were the most important physical findings. Liver enlargement was present in 103 cases, of which 37 had had a preceding infective hepatitis. Half of the remaining 66 cases were considered to have a chronic amoebic hepatitis, and the remainder a chronic non-specific hepatitis which did not respond to emetine.

70% of the cases showed abnormalities on sigmoidoscopy which were typical or suggestive of amoebiasis.

Considerable difficulty in demonstrating the vegetative forms of *E. histolytica* was encountered until we adopted the routine of examining all stools passed after vigorous purgation. Using the method described, a positive result could usually be obtained in one day.

Amoebiasis contracted in Italy responds well to standard methods of treatment, and the relapse rate is low.

Chronic amoebiasis should be considered as a possible cause of vague abdominal symptoms occurring in a soldier returning from an overseas theatre where amoebiasis is known to be prevalent.

I am indebted to the Director of Medical Services, 2nd New Zealand Expeditionary Force, for permission to publish this paper.

Middlesex County Council, in pursuance of a scheme approved in 1945 regarding the medical staffing of its hospitals, has just made sixteen senior medical appointments—five appointments of physician, seven of surgeon, three of pathologist, and one of radiologist. The salary attaching to the positions of physician and surgeon starts at £1,200 per annum and rises by annual increments of £100 to £1,800, and on proof of outstanding achievement and subject to the specific approval of the Council there may be further increments of £50 per annum up to a maximum of £2,200. For the positions of pathologist and radiologist the salary starts at £1,100, and rises by annual increments of £100 to £1,700, with further increments on a similar basis to those of physicians and surgeons up to a maximum of £2,000.

A CASE OF HYDATIDIFORM MOLE AT AGE 52

BY

A. H. CHARLES, M.B., F.R.C.S., M.R.C.O.G.

Visiting Physician, General Lying-in Hospital, London; late Adviser in Gynaecology, Middle East Forces

Apart from the advanced age of the patient this case does not present any remarkable features. It is not a record, for Feenders (1936) has reported a mole occurring in a multipara of 55. Vassbuch and Vermelieu as quoted by Sherman (1935) found twenty pregnancies in women over 50, five of whom had hydatidiform moles.

Hydatidiform mole occurs most often between the ages of 20 and 30, but if the total number of pregnancies occurring over 40 is considered hydatidiform mole appears two and a half times more frequently in this age group. Of the cases reported by Brews (1939) 37.5% were in women over 40, but 89.7% of Sherman's series of 78 cases from the Lying-in Hospital of the City of New York were under 40.

Most American authors are agreed that the best treatment for hydatidiform mole occurring in women over 40 is hysterectomy, particularly if they are multiparae. There is little reason to quarrel with this view when one considers the incidence of chorion-epithelioma after hydatidiform mole. Published figures show a wide variation in this incidence of from 5% to 31% (Nelms, 1939) (Brews, 8.3%). It does not seem reasonable to take a 1 in 10 chance of chorion-epithelioma developing in an elderly woman if she is fit for a radical operation when the mole is discovered.

Case Report

In March, 1945, a woman aged 52 consulted Major Matthews, R.A.M.C., on account of a blood-stained discharge of a month's duration. She had been married for 14 years and had one child, aged 11. In 1937 Fothergill's operation for prolapse was performed in England. In 1938 she had an abortion of a 2½-months gestation. A curettage was done after the abortion. In 1940 she had whooping-

FIG. 1.—Photomicrograph showing oedematous villi.

cough, during which a painful swelling appeared in the abdomen and gradually disappeared—possibly a haematoma of the abdominal wall. Her menses began at the age of 10 and were regular 4-5/28. She had a normal period from Dec. 31, 1944, to Jan. 4, 1945; her next period began on the correct day, but the flow ceased after 24 hours; four days later a brownish discharge appeared, and continued for a few days without remission. Since then she had had a slight loss each day.

Major Matthews found an enlarged uterus, suspected carcinoma of the body of the uterus, and performed a diagnostic curettage. The report on the curettings was anaplastic carcinoma. He referred the patient to me owing to the limited surgical facilities in his locality. She was transferred to Cairo on March 10, and on examination a large soft uterus the size of a 10 to 12 weeks pregnancy was found. The breasts were negative.

The slides and the paraffin block were sent with the patient. Major Alan Morgan examined the slides. He could not confirm the original diagnosis, and cut further sections from the block, on which he submitted the following report: "The scrapings show evidence of conception, with numerous chorionic villi and sheets of decidual cells containing vascular spaces. The villi are enlarged

owing to oedema of the central stroma (Fig. 1), the Langhans cells are frequently two layers in thickness, and syncytial cells show distinct proliferation. In my opinion this is not an adenocarcinoma, nor a chorion-epithelioma, and the swelling of the villi and chorionic proliferation are suggestive of a hydatidiform mole, possibly of the invasive type."

On March 13 examination under a general anaesthetic confirmed the previous findings; the cervix was easily dilated, and a pair of sponge forceps introduced through it withdrew typical vesicles, the largest being about the size of a pea. The cervix was closed with sutures after a gauze plug had been inserted. Total abdominal hysterectomy and bilateral salpingo-oophorectomy was then performed. The ovaries did not contain any cysts. Apart from some post-operative distension convalescence was uneventful, and the patient left hospital on the seventeenth day.

The tissue removed and the uterus were examined by Major Morgan, who reported as follows: "The curettings have the same microscopical appearances as given in the previous report, and con-

FIG. 2.—Sagittal section of uterus after fixation.

firm the diagnosis of hydatidiform mole. The uterus on sagittal section (Fig. 2) is packed with firm reddish tissue, probably a molar pregnancy, the size of a hen's egg. There is no macroscopic evidence of invasion of the uterine wall."

It is interesting to see how little the uterine contents were disturbed by the two explorations; the main mass is a firm coagulum of retained blood forming a fleshy mole in addition.

Two Friedman tests were performed after operation. In the first instance the rabbit died, but the second test, done on June 26, gave a negative result. X-ray examination of the chest showed no abnormality. The patient is well to-day.

My thanks are due to Major G. D. Matthews, F.R.C.S., M.R.C.O.G., for referring the case to me, and to Major Alan Morgan, M.D., for his pathological examination and the photographs.

The Ministry of Health reports an increase in the number of cases of venereal disease. Last year 10,706 new cases of syphilis were treated at local authorities' clinics in England and Wales. This is 1,388 more than in 1944, and more than double the pre-war total. During the war the annual total rose steadily from 4,986 in 1939 to 9,642 in 1943. There was a slight improvement in 1944, when the figure was 9,318; but the 1945 total is the highest recorded for at least 14 years. The campaign of public education, carried out since 1942 by means of advertisements, posters, films, and exhibitions, is to be continued.

Medical Memoranda

An Unusual Complication of Thiouracil Therapy

There is little doubt in our minds that in the following case thiouracil caused the severe constitutional symptoms, which included prominent adenopathy on two occasions and pancreatitis in the second attack, which necessitated a laparotomy.

Mrs. A. was admitted to hospital on Nov. 7, 1945, with a diagnosis of angina pectoris, intermittent claudication, and cardiac infarction. Her symptoms, which had started three months before, were becoming increasingly severe. The blood pressure was normal. The electrocardiogram showed inversion of the T waves in leads II and III. She was nervous and excitable, but there was no evidence of thyrotoxicosis, and the basal metabolic rate was $+2\%$. She continued to have many short attacks of chest pain, usually brought on by excitement, and as rest and sedatives produced no improvement it was decided to try to reduce the number of anginal attacks by depressing the basal metabolic rate with thiouracil (Raab, *J. Amer. med. Ass.*, 1945, 128, 249). Treatment was started with 0.2 g. three times daily, and this was uneventful for three weeks. The white cell count was maintained at 7,000 to 10,000 per c.mm.

On Jan. 29, 1946, she developed painful enlargement of the submandibular glands on both sides, with a temperature of 101°F . (38.3°C .): No other glands were enlarged, and the spleen could not be felt. The fauces were red, and there was an area of white exudate from which a smear demonstrated Gram-positive streptococci in short chains. A vesicular rash resembling cheilopompholyx appeared on the hands. The white cells numbered 7,200 per c.mm., of which 74% were polymorphonuclear neutrophils, 2% transitionals, and 24% lymphocytes. Thiouracil was discontinued and a course of sulphadiazine given. The temperature fluctuated between 100°F . (37.8°C .) and 102°F . (38.9°C .), and five days later it was 99°F . (37.2°C .); other symptoms, including the glandular enlargement, had abated, except for a dull epigastric ache which had appeared insidiously several days previously. Phenobarbitone, $1/2$ gr. (32 mg.) twice daily, was continued throughout. It was not clear whether the fever, rash, and glandular enlargement were independent of the thiouracil. The exact origin of the swelling in the neck, whether from upper cervical lymph glands or submandibular salivary glands, was also uncertain because of its great size. Accordingly, thiouracil was restarted on Feb. 8 in doses of 0.2 g. four times a day. On the afternoon of Feb. 9 there was rapid and dramatic enlargement of the submandibular salivary glands, with sudden severe epigastric pain. Thiouracil was discontinued at once. Vomiting of bile-stained fluid occurred and several loose stools were passed. That evening the temperature was 101°F . (38.3°C .) and the pulse 88. The abdomen was rigid and tender, particularly in the epigastrium and also posteriorly over the upper lumbar spinous processes. There were no sounds on auscultation of the abdomen. The electrocardiogram showed no change, and a further coronary thrombosis did not seem likely. During the night her condition deteriorated, and there was no relief from the pain after morphine, atropine, and pethidine. The next morning the temperature was 102.4°F . (39.1°C .) and the pulse 104, and the pain was worse. Its site was the upper abdomen, and it spread to the back on the left side; signs of collapse were evident. There was no jaundice or cyanosis. Urinary diastase was within normal limits. Mesenteric lymphadenopathy, mesenteric thrombosis, and acute pancreatitis were all entertained as possible diagnoses, but as peritonitis could not be excluded the patient was immediately transferred for surgical treatment.

The only abnormal finding at laparotomy was a hard generalized enlargement of the pancreas, and the gland was swollen to about twice its normal size. There was no free fluid, nor was there any evidence of fat necrosis. The abdomen was closed and the patient made good progress after administration of intravenous saline and glucose. The submandibular glands subsided slowly and some abdominal discomfort remained for a time.

AUBREY LEATHAM, M.B., M.R.C.P.

Ascariasis Causing Acute Intestinal Obstruction

Round-worms are known occasionally to cause intestinal obstruction. The following is a case in point.

CASE REPORT

The patient was a female house-servant aged 45, and was admitted to hospital on Aug. 12, 1940. Five days previously she began to have spasms of colicky generalized abdominal pain, which doubled her up and caused her to cry out. These continued until the day of admission. She had lost her appetite and had vomited a few times, bringing up about fifteen round-worms, and had passed two with her faeces. There was no history of urticaria, cough, fever, or haemoptysis during the previous weeks. On examination she was thin and a little anaemic; nothing more abnormal was found except for slight general tenderness and a doughy feeling in the abdomen. Santonin 3 gr. (0.2 g.) and calomel 2 gr. (0.13 g.) were given on admission, followed later by 6 drachms (21 ml.) of castor

oil and a belladonna and hyoscyamus mixture. The result was the passage of a large mass of tangled round-worms; this was followed by some relief of her symptoms.

On Aug. 14 the pain became very severe and was accompanied by vomiting. There were abdominal distension and a marked "ladder-pattern" of small-gut obstruction during each spasm. A diagnosis of acute intestinal obstruction caused by round-worms was made, and laparotomy performed forthwith under open chloroform and ether anaesthesia. A right lower paramedian incision revealed almost the whole of the small intestine distended with masses of coiled-up conglomerate round-worms. Two coils obstructed by especially large knots of worms were packed off, and through a small incision in the summit of each, guarded by a purse-string suture, 100 and 40 worms respectively were removed with long-pronged artery forceps. When no more could be removed from those portions of the gut the openings were closed. There appeared to be many hundreds of worms still left in the intestine. As the chief sites of obstruction had been dealt with, these were left alone and the abdomen was closed.

During the post-operative period there were slight suppuration of the wound, pyrexia (100 – 101°F . = 37.8 – 38.3°C .), general weakness, and, at first, some abdominal distension. Pituitrin and intravenous saline and glucose were given during the first day. Almost all the hair of her head fell out in the next few days. Anthelmintic treatment was recommenced on Aug. 18, repeated on the 21st and 27th, and on Sept. 1 and 3. (A change from santonin 3 gr. (0.2 g.) to oil of chenopodium 15 m. (0.9 ml.) was made on Aug. 27.) Each treatment yielded only a few worms. The patient insisted on leaving hospital on Sept. 3. When seen again on March 26, 1946, she appeared well nourished, was feeling very fit, and stated that she had had no more pain or other discomfort since leaving hospital: also that she had not passed any more round-worms. She had remained bald since the time of her previous illness.

COMMENTARY

With such a heavy infestation with round-worms it is curious that there was no history suggesting "ascaris pneumonia," nor of toxic manifestations such as urticaria. The diagnosis of the cause of the obstruction became fairly certain after the passage of the large mass of round-worms as a result of the first anthelmintic dose. It is surprising that no more worms were passed following post-operative anthelmintic treatment, and that after leaving hospital until she was seen again five and a half years later no more worms had been passed. The loss of hair was probably due to the effect of a severe illness, though under these circumstances it is usual for the hair to grow again. It should be added that the patient was of a somewhat eccentric mentality, which may explain both the gaps in the history and the almost certain eccentric eating habits leading to her heavy infection with ascari, though there was nothing clear-cut in the dietary history to suggest how such a massive infection had come about.

D. LANDSBOROUGH, M.D., B.S.

General Hospital, Chuanchow, Fukien, S. China.

Carcinoma of Colon causing Acute Intestinal Obstruction in Youth of 17

Carcinoma of the colon in adolescence, without a history of familial polyposis, is uncommon, and the following case seems to be interesting enough to warrant publication.

CASE REPORT

A youth just 17 was admitted to the West Middlesex County Hospital in May, 1939, with a five-day history of colicky abdominal pains situated in the umbilical region and associated with absolute constipation. He had vomited several times on the two days before admission.

On examination gross tympanitic distension of the abdomen was found, but no mass was palpable and rectal examination was negative. He denied any previous bowel trouble; he had always enjoyed perfect health. A diagnosis of acute small-gut obstruction of uncertain aetiology was made, and laparotomy advised. A typical "ring" carcinoma of the splenic flexure was found, with gross distension of the proximal colon and small intestine. Caecostomy was performed. Three weeks later resection of the growth (Mr. W. J. Ferguson) was done, with end-to-end anastomosis, and subsequently the caecostomy was closed. He made an uneventful recovery. The operative diagnosis was confirmed by microscopy. On subsequent questioning no family history of colonic neoplasm could be elicited, nor could polypi be demonstrated in the excised specimen.

A carcinoma of the colon of the adult type was an unexpected operative finding. The previous history gave no clue as to the correct diagnosis, and failure to recognize it could, I consider, be excused. A further interesting point is the long survival after the resection, the patient being recently seen in perfect health some seven years after operation. This is contrary to the usual experience in intestinal cancer in the young, early recurrence being only too frequent.

J. SCHOLEFIELD, F.R.C.S.

Reviews

MYOMECTOMY AND OVARIAN CYSTECTOMY

The Technical Minutiae of Extended Myomectomy and Ovarian Cystectomy. By Victor Bonney, M.S., M.D., F.R.C.S., F.R.A.C.S. (Pp. 282; illustrated. 30s.) London: Cassell. 1946.

Probably no one of this generation has done more for the development of gynaecological operative technique than has Victor Bonney. Chief among the subjects with which his name will always be associated is the development of radical surgical methods (the Wertheim operation) for treatment of carcinoma of the cervix. But no less should he be honoured for his insistence on conservative surgery—when that is possible—for non-malignant gynaecological conditions, notably the substitution of myomectomy for hysterectomy, and ovarian cystectomy for ovariectomy. Perhaps because conservatism has less “news value” than radicalism, Bonney’s achievements in this field have never received the notice they have undoubtedly merited; even to-day the ease with which ovarian cysts can be shelled out is not fully realized, and too often one hears of the needless sacrifice of ovaries, and even of complete castration, in young women.

In his well-known book written in conjunction with the late Sir Comyns Berkeley (*A Textbook of Gynaecological Surgery*) an excellent account is given of both myomectomy and ovarian cystectomy, but the discussion on these operations, and the details of technique, had of necessity to be compressed in order to maintain a balance with the other contents of the volume. This restriction Bonney has now removed by a new publication dealing exclusively with these two operations. In it the fruits of a ripe, and probably unrivalled, experience are presented with the author’s customary vigour and enthusiasm. Every aspect of the subject is discussed, and no fewer than 241 line drawings—each made by the author himself—are included to illustrate the various manoeuvres. These illustrations are specially noteworthy, for by them the author’s meaning is conveyed with a greater directness and clarity than would be possible were the more “beautiful” type of medical illustration used.

That it is possible to conserve the uterus when massive fibroids are present, or when the tumours are so numerous that 100 or more are encountered, or when a large fibroid awkwardly distends the lower part of the cervix, may come as a surprise; so also may the conservation of ovarian substance when a cyst weighing 20 lb. or more is found to be filling the abdomen; yet all these events are recorded by the author, and their appropriate treatment is discussed. Of particular interest is a case in which 40 fibroids were removed, weighing in aggregate 21 lb.; and another in which 6 dermoids were removed—3 from each ovary—and the woman later became pregnant on two occasions. In all, the author records 806 personal cases of myomectomy with a mortality of 1.1%. Ovarian cystectomy he has performed 301 times without a death. Every type of operation—simple myomectomy in all its forms, multiple myomectomy, cervical myomectomy, caesarean myomectomy, block uterine excision, adenomyomectomy, and ovarian cystectomy—is depicted, and the means of dealing with almost every conceivable difficulty discussed.

This is a remarkable book and one which will take an honoured place alongside the already widely known *Gynaecological Operations*. To the gynaecologist its appeal is certain; to the general surgeon whose practice includes pelvic surgery it can be recommended as the best account we have seen of this highly important though strangely neglected field of conservative surgery.

DRUG ADDICTION

Narcotics and Drug Addiction. By Erich Hesse, M.D. Translated by Frank Gaynor. (Pp. 219. \$3.75.) New York: Philosophical Library, 15, East 40th Street.

This book has been translated from the German, “published and distributed in the public interest by the Alien Property Custodian” in the U.S.A. It is a useful book of reference for those wishing to have available an account of the different substances which are commonly found to produce addiction. It contains not only pharmacological but chemical information,

and a limited but well-chosen selection of cases illustrating the effects produced by the narcotic, and the results on the individual. All the opium derivatives are discussed together with artificial products like heroin and eucodal; cocaine, mescaline, hashish, and kava-kava are also considered. Not everyone knows that atropine and scopolamine have been used as intoxicants, and that muscarine from the *Amanita muscaria* has also: it produces an urge to keep talking incessantly. There is also a useful discussion on alcohol and tobacco.

While the effects of opium derivatives and of cocaine are well known, those of mescaline are less so. Heffter has given a description of its effect on himself. He lay down in a darkened room and closed his eyes.

“Despite the darkness, after-images were remarkably sharp and lasting. The after-images were frequently followed by series of pictures in gorgeous colours, some of them like carpet designs and mosaics, others showing intertwined coloured stripes moving at lightning speed. Colourful rays of intense brilliance shot across my dark field of vision, like projectiles from a firearm, but moving even at a higher speed. All colours were represented. These visions were followed by a series of beautiful landscapes, characterized primarily by a wonderful colour effect. Thus, for example, I saw the broadwalk of the Nervi beach; the branches of trees of a remarkably rich red colour hung over the walls. . . . Often I saw also the interior of richly decorated banquet halls, their walls, ornaments and chandeliers decorated with colourful jewels, opals and pearls. It was odd that the ceiling sometimes seemed to be down below, or hanging vertically at the side: this experience produced a violent vertigo and an increasing sensation of nausea. The visions disappeared as soon as I opened my eyelids. A very remarkable symptom was the loss of the sense of time; what I estimated to be half an hour was really just a few minutes.”

There is also a useful account of the effect of hashish, or Indian hemp, given by Joel and Fraenkel, of which the following is an extract:

“One of the first signs indicating that the toxin is beginning to take effect is a dull sensation of premonition and uneasiness. Something strange, something inevitable seems to be approaching. Next, activity wanes, and a sensation of helplessness and anxiety may be experienced. If the addict yields to this state, he will soon realize that he is caught. Scenes and series of scenes of experiences long past flash on, entire scenes and situations are relived. First, they arouse interest, occasionally pleasure, and finally, when there is no escaping from them, tiredness and torment. And this compulsory state cannot be broken by saying to yourself: ‘This is nothing but the effect of the toxin.’”

It is interesting to learn that the reputed aphrodisiac effect of hashish is produced only in orientals and not in white people.

JOB PLACEMENT FOR THE DISABLED

Job Placement of the Physically Handicapped. By Clark D. Bridges, Director of Conservation Services, Zurich Insurance Companies, Chicago. (Pp. 329; illustrated. \$3.50 or 17s. 6d.) London and New York: McGraw-Hill Book Company, Inc. 1946.

A national scheme for the reablement and resettlement of our disabled workers is already with us; comment has been made in these pages upon the capabilities of the officials who will work the scheme, and upon the training they ought to receive. It is therefore appropriate and welcome to see a book which will go a long way to provide the basic knowledge needed by everyone, whether in Ministry or industry, who is asked to provide for disabled men but who has no grounding in medicine. But this is more than a textbook of medicine simplified. With good sense the author has included only those illnesses which most commonly occur, and his emphasis is upon the disability caused in each case, the conception of disability throughout being as optimistic as the facts will allow. Parallel to the descriptions of disease are analyses of the many physical demands which work may make upon a man in industry: his posture, his possible output of energy, his contortions, his environment; the dangers and toxic hazards he may have to endure, are each dealt with separately and defined as carefully as in any dictionary. This analysis is the basis of job-analysis, which all will agree we should postpone no longer. To assess a man as a working unit and to assess what his job will demand of him is the logical way of finding him satisfactory work and ultimate contentment. The doctor may know his man, the works manager and foreman may know the job, but it is time that each knew more of the opposite side of the problem; in this lies the value of the book. It is based upon field research,

and the wealth of material is presented ingeniously and with accuracy. Though it is evidently written with the close co-operation of medical men there is a tendency for the space allotted to certain diseases to exceed their relative importance, and others suffer thereby. On the whole the balance is good, for the field to be covered is uncomfortably wide. The American phraseology and the inclusion of references to United States laws and institutions should by no means discourage people in Great Britain from reading so valuable a contribution to the subject as this. Whatever his nationality, the problems of a handicapped man in a post-war industrial world must be much the same.

PSYCHOLOGY OF WOMEN

The Psychology of Women. A Psychoanalytic Interpretation. By Helene Deutsch, M.D. Foreword by Prof. Stanley Cobb, M.D. Volume I: Girlhood. (Pp. 312. 21s.) London: Research Books Ltd. 1946.

Dr. Helene Deutsch is a strict psychoanalyst and was a personal pupil of Freud. She has now set out to conduct a study of her own sex. The present volume, the first of the series, deals with girlhood studied along psychoanalytic lines. Here we have displayed, with case histories and narratives, the results of the Oedipus situation, castration complexes, penis envy, and of oral, anal, and urethral eroticism, which are the universal background of Freudian psychology. The book is persuasively and clearly written, and there is at least an apparent logical sequence between these mental adventures of the early years and the resultant manifestations of female eroticism, masochism, the "active" masculine woman, homosexuality, and the rest. There is no doubt that neurotic traits and some not so neurotic traits can be explained by tracing them to these emotional reactions of the young child; and, inasmuch as the patient is convinced of the validity of these explanations and is thus given a satisfactory face-saving device so that she can reorganize her attitude to life, she will be helped and perhaps cured; but that all behaviour, even all abnormal behaviour, is to be traced to these few common denominators is not so certain. However, full and prolonged psychoanalysis works; therefore where the physician and the patient have time to undergo the discipline is entirely justifiable. Certainly every serious student of psychology should study the subject and its conclusions, but if he can help his patients to a better understanding of themselves and a greater security of emotional attitude by shorter methods so much the better for him and them. This book will therefore be useful to the knowledgeable but must not be taken too seriously by the uninformed.

GYNAECOLOGY FOR NURSES

Gynaecology. A Handbook for Nurses. By Gladys H. Dodds, M.D., F.R.C.O.G. (Pp. 202; illustrated. 10s. 6d.) London: Faber and Faber. 1946.

Although the author states that "this book has been written to provide the nurse with the fundamentals of gynaecology," one gains the impression on reading it that this is rather a book for the specialist nurse or sister. In other words, there is too much detail in parts, and subject matter is included which is not entirely relevant. The chapters on ante-partum haemorrhage and pregnancy toxæmias should be excluded, and judicious pruning of ante-natal care and post-natal care would help to reduce the plethora of fundamentals that the student nurse has to assimilate. The gynaecological nurse is not a midwife, and here "a little learning" would be "a dangerous thing." Three operations are described for shortening of the round ligaments, but Bonney's plecting operation is not mentioned. Alexander-Adam's operation is seldom, if ever, done nowadays.

The book is well produced and the illustrations are excellent. The above criticisms do not condemn the book and the reviewer hopes they will serve to have the material groomed into a minimum of valuable data from the nurse's point of view.

Notes on Books

A Guide for the Tuberculous Patient, by Dr. G. S. ERWIN, was noticed with warm approval in this column when it first appeared in 1944. A second edition has now been published by William Heinemann Medical Books, Ltd., at 3s. 6d. New sections have been added on "nerves," social statistics, and aviation. In no other disease of common occurrence is the intelligent co-operation of the patient more necessary. Dr. Erwin's little book will save the physician's time and advance the patient's understanding.

HANNS SACHS, author of *Freud: Master and Friend* (Imago Publishing Co.; 9s.), was a member of that inner circle which gathered round Freud and were largely responsible for the spread of the doctrines formulated by the master all over the world. This biographical sketch—it is no more—is admittedly a panegyric of the father of an increasingly large family, but it is pleasantly and most sympathetically written and gives the reader an excellent picture of the genius who was so extravagantly execrated and perhaps as extravagantly praised by learned men and others throughout civilized society. Freud's rigid adherence to what he regarded as first principles is described, and it explains his apparent intolerance of those who differed from him and broke away from the original circle to become bitter critics and opponents. The final chapters give a moving picture of Freud's fortitude in bearing these defections and later the ravages of a painful and fatal malady needing repeated severe operations and culminating in persecution and exile. It is gratifying that this country afforded him asylum and such peace as was possible in the last days of a really great man.

Atlas to Surgical Approaches to Bones and Joints, by TOUFFIC NICOLA (New York: The Macmillan Company; 25s.), consists of a series of simple but adequate diagrams of the bones and joints which are accessible to surgery. The diagrams are skilfully conceived and well drawn, and descriptions are cut down to a minimum. It will be difficult to imagine a better exercise for the student than to copy the diagrams, while from the point of view of the demonstrator of surgical anatomy the book is a gold mine.

Preparations and Appliances

A CONTAINER FOR THE CULTURE OF GONOCOCCI IN CARBON DIOXIDE

Dr. JOHN A. BURGESS, V.D. Officer, West Riding County Council, writes from Wakefield:

The usual laboratory methods of culturing gonococci in an atmosphere containing some carbon dioxide are unsuitable for use in venereal disease clinics where culture plates are often inoculated and placed in the incubator by the nursing staff. The container described below has been found to be simple and satisfactory in use at a venereal disease clinic. It occupies a comparatively small space in the incubator and is economical in the amount of carbon dioxide-air mixture used.

The container consists of a cylindrical tin box measuring 103 mm. in height by 75 mm. in diameter. It has a quarter-turn screw-on air-tight lid through which has been fitted a small brass tube with a rubber outlet valve similar to the type found in double bellows. Inside the container there is a wire rack which will hold 8 Petri dishes (each 60 mm. diameter by 12 mm. deep). The side of the container near the base has a brass tube fitting, with an inlet valve of the same type as that on the lid.

Method of Use.—The culture plates are inoculated in the usual way and placed in the wire rack. The latter is inserted into the container and the lid screwed on. The inlet tube at the base of the container is then connected to a rubber tube from a gas cylinder containing 8% carbon dioxide in air. Sufficient of this gas mixture is run in to displace all the air in the container (approximately 400 ml). The CO₂ mixture being heavier than air displaces the latter upwards and out through the outlet valve. The tube from the cylinder is then disconnected and the container placed in an incubator at 36° C. for about 48 hours. At the end of this time the culture plates are removed and sent to the laboratory for examination.

The container has been made for me by Messrs. C. F. Thackray, Ltd., Leeds, from whom similar containers can be obtained.

SATURDAY SEPTEMBER 28 1946

CARE OF THE CHRONIC SICK

The Institute of Almoners is a relatively new body incorporating the Institute of Hospital Almoners and the Hospital Almoners Association. A suggestion made by Sir Ernest Rock Carling was taken up by the Institute early this year, and a questionnaire on the care of the chronic sick was addressed to almoners at the 350 hospitals throughout the country which provide an almoner service. An analysis of the replies received bears out the view of Dr. Sturdee and Lord Amulree¹: "Not only is the problem of the treatment of the chronic sick not being met, but most people do not realize that there is a problem."

Almoners everywhere report a disturbing lack of accommodation for the chronic sick and particularly for those suffering from inoperable cancer. In Carlisle "there are available only six female and six male beds for the chronic sick." Municipal hospitals at Hull "are now so overcrowded that it is difficult in some of them to get a dressing trolley between the beds." Other accounts reflect an administrative dilemma. Either patients die miserably at home or they occupy for months, or even for a year or longer, beds intended for more acute cases. Where there is accommodation either in municipal hospitals or in public assistance institutions it is too often in "old workhouses" or in "a grim, depressing, and ill-cared-for place," or else in "out-of-date buildings, quite unsuitable for the purpose of nursing patients who need especial care, in surroundings calculated as far as possible to give them confidence and cheer them in their last illness." Proper segregation is impossible and cases of inoperable cancer may be in one small ward with senile patients, noisy mental cases, and even "isolation cases from the maternity ward." In public assistance institutions conditions seem to vary greatly, and in general provision is "for the senile rather than the sick, and even less for the suffering." A further disadvantage is the old Poor Law stigma which still clings to so many of these places. This is especially the case in those areas where admission can be obtained only by application to the relieving officer, and according to one account "relieving officers have not always the right attitude." Another administrative difficulty is "the law of settlement, which may prevent a patient being transferred from a voluntary hospital outside his county direct to a public assistance institution without at least one night at home." The same difficulty arises when a patient has to go to the hospital which serves the district in which

he lives, even though it may not be nearly so accessible as a nearby hospital administered by a Public Assistance Committee. Fair comment on the combined effects of lack of accommodation, difficulties in administrative areas, and often justifiable dislike of poor accommodation as is available is provided by the Godalming report which concludes: "fortunately she here sooner than expected." The gloom of this and other case histories is not relieved by such background as the daughter who had a "nervous breakdown from strain of nursing him"; a wife "worn out with nursing him at home and ill herself"; a husband who nursed his dying wife until he was in debt, "in danger of losing his job" and "in a completely exhausted state."

The picture presented by the Institute of Almoners is not all black. In some few areas there are both voluntary and municipal hospitals making more than adequate provision for at least some of their chronic sick. Others are well cared for at their own homes by district nurses. Almoners were practically unanimous in describing local district nursing associations as efficient and cooperative. The home help service seems to be developing, though slowly and somewhat feebly and only in larger towns. The problem of the chronic sick is a large one and one that is not likely to grow less. It seems possible that by 1950 there will be five million people in Great Britain over the age of 65. Their needs are many and it is not easy to visualize any one scheme which will meet all of them. There is probably a place for homes and hospitals for the dying in any scheme that may be devised. There are a handful of such homes scattered throughout England and Wales where those who are in the last stages of illness have preference over those who still have some capacity for living. Their great disadvantage is the depressing effect on both patients and relatives of this segregation of the dying. But for selected patients who are aware of their condition the special care and attention that can be given to them at such homes is of value. As Cunningham Dax and Reitman² pointed out recently, there is an increasing need for special psychiatric hospitals for the aged where with proper treatment, especially in the affective group, rehabilitation can be achieved in a fair proportion of cases. There is a need, too, as Mungo Park suggested, for infirmaries where the simple types of senile dementia who are not in need of special psychiatric treatment could be looked after. The same applies to elderly patients suffering from cancer who have passed the stage where they might benefit by treatment but still need a great deal of nursing. Probably such patients could best be cared for in an annexe to a cancer hospital. Fractures in the elderly need much more than orthopaedic attention, but might well form a special group within the orthopaedic department. Much the same arrangement of a block or a single ward for any type of chronic sick might profitably be arranged within each and every department of the larger hospitals. Sir Alexander Macgregor suggested to the Glasgow Corporation in 1944 that 10 to 20% of the total beds of general hospitals should be allotted to chronic sick. Most hospitals tend to give priority to acute cases

³ *British Medical Journal*, 1946, 1, 736.

⁴ *Ibid.*, 1946, 1, 549.

and to discharge or transfer the chronic sick unless they are of special interest for teaching purposes.

These considerations apply to one large group of the elderly chronic sick. Another group needs only an expansion of existing district nursing facilities. Yet another would be more than content with a regular home help service. Others still could look after themselves in well-designed hostels with only occasional nursing or medical supervision. All these groups merge imperceptibly one into the other and all of them may need at some time expert diagnosis and treatment. They overlap, too, the increasingly large section of the population which is not old and infirm but merely old. The problem of the chronic sick is closely related to that of provision for old persons generally. Clearly, men and women who are old and sick and not likely to recover are just as deserving of the best kind of care as those for whom there is hope of recovery. The provision of that care will tax the administrative ingenuity and the clinical and nursing skill of all concerned, even assuming a more humane, enlightened, and individual outlook towards the chronic sick than has hitherto been manifest. The creation of an adequate and comprehensive scheme to cover these needs is becoming urgent.

BRITISH-SWISS MEDICAL CONFERENCE

The Swiss Academy of Medical Sciences last week entertained a large number of British medical men and women at a British-Swiss Medical Conference held at Basle. Those who were fortunate enough to be present will long cherish the memory of a week which, for the British visitors, passed all too quickly in a city which blends the old and the new in an architectural unity of surpassing charm and vigour. Of the new, the British visitor took home with him an impressive recollection of the new university building completed during the war, and more especially of the Bürger-spital, which was opened last year. This new building is a landmark in hospital development and by contrast shows up the deficiencies of so many of our own institutions. But what struck the British guests even more than this lovely city untouched by war was the sincere friendliness of their Swiss hosts and the Swiss people, the sense of unity they had with British democracy, the eagerness and anxiety with which they had watched the fall and rise of our fortunes of war, the feeling, perhaps, of obligation felt by the Swiss nation towards Britain, which in its victory had preserved the democracy of Switzerland. In his thoughtful address of welcome to the Congress Prof. Edgar Bonjour, Rector of the University of Basle, stressed the elements common to both countries. "What counts with both people alike," he said, "as the only genuine goal of all political exertion is not might but freedom, the rule of law, justice, and moderation. This system fully recognizes the overwhelming importance of the individual, with whom every renewal, and therefore also every culture capable of establishing permanent values, ultimately begins. In both States the individual is constitutionally safeguarded against the encroachments of the multitude."

The relations between Basle University and England are described with much point and interest by Prof.

Bonjour in an article published in a special edition¹ of the *Schweizerische Medizinische Wochenschrift* to commemorate the Conference—an edition which includes in full the papers read at the scientific sessions, and short illustrated articles on the medical schools and faculties of Great Britain and Ireland; an edition, moreover, which in its format and printing is worthy of the high tradition of one of the oldest centres of printing in Europe. The University of Basle was founded in 1460. In the Basle matriculation rolls of the sixteenth and seventeenth centuries "one is amazed to discover," writes Prof. Bonjour, "how many English names which figure there have left their mark on history." Perhaps one of the most interesting links between England and Basle is to be found in the person of that mocker of human folly—Erasmus of Rotterdam. Intense individualist and lover of personal liberty, he found England and Basle two places congenial to his temperament. He completed his New Testament at Cambridge and had it printed at Basle, where he died. At Basle, also, two men famous in medical history threw down their challenge to authority. The turbulent Paracelsus burnt the works of Galen and Avicenna in the market-place, and from the printing presses of Basle came the *De Fabrica* of Vesalius in 1543. Familiar enough to Britons is the Basle-born Holbein, whose pen-and-ink sketch of Sir Thomas More and his family is one of the treasures of the Basle Art Museum.

The Conference last week enabled the Swiss—in particular the Baslers—and the British to renew once more their centuries-old friendship. Our Swiss colleagues reminded us on more than one occasion of the intellectual isolation into which the war of 1939–45 had placed them and welcomed this occasion for the exchange of information and ideas. A first summary of the papers read at the meeting appears elsewhere in this week's *Journal*. The British speakers and subjects were chosen by a committee under the auspices of the Royal Society of Medicine, to whose efficiency in organizing the British side of the Conference we would pay tribute. A varied intellectual fare was provided for our Swiss hosts and showed, we may believe, that in spite of our preoccupation with practical issues during the war years fundamental research in medical science was pursued with vigour. Our Swiss colleagues in return gave in full measure of the fruits of their work. If the Swiss have suffered intellectual isolation during the war we on our part have been isolated from the graces and comforts of civilized life, and these we found in abundance in the generous hospitality of our hosts and in the intellectual and physical amenities of Basle and Switzerland—a welcome refreshment of mind and body. Among the places of interest visited not the least were the chemical factories for which Basle is famed and in which the devices of modern technology have reached such a high pitch of application.

It is not possible here to mention by name the many Swiss doctors who in so unobtrusive a fashion gave freely of their time and energy to making the Conference the outstanding success it undoubtedly was. It will not, however, be invidious if we refer especially to Prof. Karl Wegelin, the President of the Swiss Academy of Medicine, who,

urbane and witty, was always apt to the occasion with well-chosen phrases in good English, whether at the scientific sessions or at the Banquet in the hotel on the bank of the Rhine. He was ably seconded by the Secretary-General of the Academy, Prof. A. Gigon, chief editor of the *Schweizerische Medizinische Wochenschrift*. It was to Prof. Gigon that the idea of such a conference occurred, an idea which he did not relinquish until it took shape; and once it had taken shape he did not cease to labour at all the many details of organization which make or mar a meeting of this kind. It is to be hoped that the time will not be long before we in this country will be able to make a fitting return by entertaining Swiss doctors on British soil.

STREPTOMYCIN

Antibiotics¹ are substances elaborated by micro-organisms which act as antibacterial or antifungal agents. It is attractive to postulate that these substances are formed by their producers as a defence mechanism. They have often a very marked, specific, antibacterial effect against important human pathogens.

Penicillin,^{2,3} which is a wholly British discovery, is the most successful antibiotic so far exploited therapeutically, but there remain many organisms pathogenic to man which are insensitive to penicillin and the sulpha drugs, or demand for effective control of the infection doses so large as to be toxic to the host. It is customary to reserve the term antibiotic for a substance of natural origin and to exclude from this designation synthetic antibacterial substances such as the sulpha drugs. Gramicidin⁴ is an antibiotic finding increasing favour in surface wound dressings, but streptomycin,⁵ an American discovery, is showing great therapeutic promise in combating Gram-negative bacilli and *Mycobacterium tuberculosis*. Penicillin is a purified metabolite of the aerobic culture of the green micro-fungus *Penicillium notatum* (Westling's original culture was made from the decaying herb hyssop from Norway), and streptomycin can be somewhat similarly made by filtration of the product of aerobic culture of the ray fungus, originally isolated from soil, *Actinomyces (Streptomyces) griseus* (not to be confused with either the human disease actinomycosis or with streptococci). It was found, by its isolator Waksman's collaborators,⁶ to have a wide and intense potency in animals, and after a very few months of scattered American biochemical effort the pure base and crystalline salts were prepared. It is thought significant that penicillin—an acidic substance—should have maximal action on Gram-positive bacteria and that streptomycin—a base—should have maximal action on the Gram-negative series.

The pharmacological development of streptomycin in America is proving very like that of penicillin in England, and, as the first few clinical observations with crude concentrates showed such promise, the American Streptomycin Clinical Trials Committee, under the chairmanship of Dr. Chester Keefer (Harvard), has been set up to control location and method of clinical trials and to assess results before the general release of the substance. The Committee buy the entire output (some 35 kg. a month in May, 1946) of the ten firms who have subscribed \$500,000 to the Committee for this purchase. Similar controlled clinical trials are about to start in England under the aegis

of a committee appointed by the Medical Research Council to exploit the pilot-scale production of streptomycin which is being organized by the Ministry of Supply.

It is too early to assess accurately the American clinical results, but it is almost 100% effective in tularemia (rabbit fever), which though rare in England gives rise to some 1,000 serious cases a year in U.S.A. In the residuum of bacterial infections of the urinary tract which are insensitive to penicillin and/or sulpha drugs considerable success has been reported ranging up to 100% elimination of *B. proteus* and *B. pyocyaneus*. In tuberculous meningitis great promise has been shown, though residual nervous or hydrocephalic lesions often remain, and all strains of *Mycobacterium tuberculosis* seem sensitive in some degree. In pulmonary tuberculosis, for which probably the minimal effective trial period may be 5 years, Dr. Corwin Hinshaw (Mayo Clinic) and Dr. Walsh MacDermott (New York) report considerable therapeutic possibilities with streptomycin in extension of Dr. Feldman's Mayo Clinic demonstration of its value in experimental guinea-pig infections. (Penicillin will, of course, tend to repel some of the secondary bacterial invaders in the tuberculous pulmonary lesion.) Treatment is a great trial to the tuberculous patient, because it involves at present some six daily injections of the equivalent of about 600 mg. of the pure base, over perhaps six months. Cost has to be considered, with the present price of the substance at about \$15 a gramme and the lowest likely price in full production falling to \$5 a gramme, but if this is weighed against the long sanatorium treatment and even longer subsidy for the patient and his dependants it is hardly significant. Dosage is to be calculated by dry weight of base, equilibrated against the standard powder of 1,000 units per mg. potency, but this introduces the slight complication that the soluble salts (hydrochloride 842 units, sulphate 798 units per mg.) have a lower unitage than the base. Plague and leprosy are other diseases in which the effect of streptomycin is being investigated. Streptomycin, though rather more costly than penicillin, is more stable in aqueous solution and dry form, and it can be heat sterilized. Being relatively stable at acid pH levels it would survive passage through the stomach, but it has so far not been possible to give effective treatment by mouth (a very desirable route) because adequate concentrations cannot be maintained in the blood, probably owing to simultaneous excretion and absorption from the gut.

It is important to stress that a complete and final opinion on the therapeutic value of streptomycin, particularly in tuberculous infections, cannot be expected yet, and that streptomycin is unlikely to be available either in America or England for use outside the official trials for some time. The unwary philosopher may ask himself whether, with streptomycin complementary to penicillin, there will be any pathogenic bacteria for human beings to die of in the Brave New World.

CIVILIAN DEATHS FROM AIR BOMBARDMENT

The Statistical Bulletin of the Metropolitan Life Insurance Company for July, 1946, contains a useful article, under the above heading, which summarizes the available data on British civilian loss of life amounted to something over 60,000 deaths, more than two-thirds in the first "blitz" between August, 1940, and June, 1941. French losses were almost as heavy, nearly 54,000, more than two-thirds of them in 1944. In proportion to population the Netherlands suffered more than any other ally; 30,000 are estimated to have perished in the dastardly raid on Rotterdam. No figures seem to have been available with respect to Russia and Poland; Norway lost 1,000 lives. The Axis Powers

said heavily for their choice. The United States Strategic Bombing Survey estimates German losses at over half a million, and Japanese losses as between 360,000 and 175,000; the two atomic bombs are thought to have killed about one-third of this total, 105,000 to 120,000; but the most destructive single raid is thought to have been that on Tokyo on March 9, 1945—the estimate is 85,000. These are statistics of deaths alone. In time a medical and statistical study of all the effects of air raids, mental as well as corporal, will no doubt be made. The psychological effects have been, perhaps, less serious than was expected before the attacks began, but a comprehensive study requires leisure.

DR. OLIN WEST

The centenary session of the American Medical Association will be held in Atlantic City in June next year. Already plans are afoot to make it "the greatest medical assemblage that the world has ever known." At its annual meeting, which took place this year at San Francisco, the House of Delegates unanimously appointed Dr. Olin West as President-Elect. This is a remarkable tribute to the man who has been Secretary to the A.M.A. for the last twenty-four years.

Olin West graduated from Howard College in Alabama, practised at Nashville, and was instructor and later associate professor in the medical department of Vanderbilt University. In 1910 he became director of the Rockefeller Sanitary Commission and the International Health Board in Tennessee, a position which he held for eight years. Then from 1918 to 1922 he was secretary and executive officer of the Tennessee State Board of Health. It was at this stage, following the death of Dr. Alexander Craig, that Dr. West became Secretary to the A.M.A. Later he combined the functions of Secretary with those of General Manager. Dr. George F. Lull, of Chicago, has now succeeded Dr. West as Secretary.

At San Francisco the address of the President-Elect was a characteristic compliment to the staff of nearly 700 whose activities he had directed for so long, and concluded with a statement on the importance to America of "an untrammelled and idealistic profession." Dr. West's unopposed election to the presidency of the A.M.A. and the ovation which greeted his presentation to the House of Delegates were a well-merited recognition of the steadfast manner in which he has supported the ideals and dignity of the profession in the United States for a quarter of a century.

RAG FLOCK

Rag flock is manufactured mostly from strips of cast-off clothing and carpets. This material is collected mostly by rag-and-bone men, who go from house to house with a barrow and scavenge for the material in tips and dumps. Considerable amounts of material are imported from abroad, particularly from the East, including used Army clothing, underclothing, surgical dressings, and sleeping-bags. The rags may be cleansed, but dirty flock can be produced at a cost of about £5 a ton less than that which has been washed. Manufacturers who carry out their obligations are therefore at a serious disadvantage. The rags, washed or unwashed, are dried and then disintegrated in a laniator (laniate means "to tear to pieces"); the rags are conveyed on a belt to a rapidly revolving cylinder studded with steel teeth, which tears them into shreds, and they emerge from the machine a fluffy resilient mass. The flock is used in the manufacture of bedding and upholstery. There do not appear to be any authenticated cases of

infectious disease from mattresses filled with dirty rag flock, but the risk may be assumed to exist. In any case it is undesirable that anyone should have to sleep on unclean bedding. There is also a risk to the health of the workers who handle the flock, apart from the presence of vermin in it.

An attempt to control this material was made in the Rag Flock Act, 1911; the Rag Flock Amendment Act, 1928; and the Public Health (London) Act, 1936 (Section 136); but an inadequate definition of rag flock and too small penalties for contravention of the law have defeated the intention of these Acts. An Interdepartmental Committee was therefore set up in 1938 to make recommendations to ensure proper cleanliness of rag flock used for the manufacture of upholstery, bedding, and other household furniture in Great Britain. Its report and recommendations are now published.¹ These include the registration of all premises used for the manufacture of rag flock and inspection by local authorities. It is further suggested that it would be wise to apply these regulations to premises in which any kind of filling material is used.

THE REHOUSING OF BRITAIN

The five-figure totals in the latest housing returns issued by the Ministry of Health appear encouraging, as all big figures are apt to do, but they have to be measured by the dire need of housing brought about by war damage and by the cessation of building for six years. In England and Wales, up to the end of June, 12,000 new permanent houses and over 30,000 temporary houses had been put up; 20,000 unoccupied houses had been requisitioned for residential purposes, and many thousands of existing premises had been converted and adapted for family units. The new permanent houses under construction numbered over 100,000 and the temporary houses nearly 22,000. Nearly half a million operatives, excluding prisoners of war, are engaged in tackling the housing problem. The Midlands stands highest in the number of houses completed, and the north-western area—Lancashire and Cheshire—in the number under construction. In London something like 94,000 war-damaged or war-damaged houses have been or are in process of being rebuilt, repaired, and made habitable.

The Ministry's housing returns, presented to Parliament just before the recess, give all these figures and many more; but to the departmental statistician a house is just a house, and no hint is given as to size, type, or position. When a huge demand is being met by mass-production the tendency is to be impatient of any variation of pattern, and, for anything we know, all these thousands of houses which are coming into view, whether they are built by housing authorities or under licence by private builders, may be six-roomed boxlike dwellings, suitable to a family of three or four. According to the last census nearly 22% of the family units in this country consisted of two members, and this proportion is not likely, with a diminishing birth rate, to have lessened since 1931. What is being done for the housing accommodation of single persons and of old couples? The widespread provision of a standard size of house to meet the needs of families which vary widely in size will create new social problems.

We announce with much regret the death of Dr. T. Watts Eden, consulting obstetric physician to Charing Cross Hospital and consulting surgeon to Queen Charlotte's and to the Chelsea Hospital for Women.

CONDITIONS DESIRABLE FOR THE RAPID PROGRESS OF GERONTOLOGICAL RESEARCH

BY

V. KORENCHEVSKY, M.D.*

(From the Gerontological Research Unit, Oxford)

The conditions necessary for the rapid progress of gerontology are much the same as those required for the rapid advance of any abstruse problem of science or medicine. In the first place the very great difficulty of the problem of ageing must be strongly emphasized. It is as difficult as, or perhaps more difficult than, the splitting of the atom, provided that the aim of gerontology is fully faced. This aim is not only a longer life but a stronger one—"to add life to years, not just years to life"—not only prevention of the premature appearance of senile decay but also elimination of those pathological features which are not necessarily associated with normal old age, since they are not present in some rare cases of less pronounced pathological ageing. As ageing starts very early, actually with the normal process almost the whole of the span of human life will be changed, and therefore in some distant future man will probably become in some respects a different creature.

In short, science and medicine confront the task of preventing the present definitely premature and pathological ageing.

Here, however, is another great difficulty, because we do not know what are normal ageing and normal old age, what is a normal span of life, and for how long in normal ageing wear and tear could be prevented in different organs and tissues. Moreover, the basic elements and conditions of normal life, such as proper nutrition, are most probably still very far from ideal in spite of the truly remarkable progress in this field of physiology and medicine.

At the present time, in geriatrics (the medical treatment of old age) the greatest pitfall appears to be the temptation to use stimulating compounds only, of any origin and structure, in order to prevent pathological ageing (Dr. Voronoff's glandular grafts, hormones, Prof. Bogomoletz's reticulo-cytotoxic serum, etc.). The danger and disadvantages of these geriatric methods are twofold: (a) A degenerated old tissue or organ cannot stand vigorous stimulation, just as a tired horse, when whipped to do extra work, cannot withstand the strain and suddenly collapses from heart failure. (b) The causes, producing decreased function or morphological changes of certain organs and tissues and acting from elsewhere, are not removed by stimulating these organs. Therefore with such treatment the basic causes of ageing of organs or tissues will still be present and will continue to produce fatal effects.

The "elixir of life" appears to consist mainly in elimination of all abnormal causes of ageing, and not in the use of stimulating compounds only. This statement, however, should not be misunderstood. Of course, various stimulating compounds (vitamins, hormones, etc.) are naturally present in the organism, and their absence or decreased production might also come one of the important causes not only of premature ageing but of death. Therefore their role in geriatrics might be very important and, in some cases of deficiency of these compounds, be not only rejuvenating to a certain degree but might actually save the life of the organism. With regard, however, to the general basic causes of ageing and the respective approaches to their treatment, it is important to allocate a proper place to stimulants and urge their correct application in geriatrics.

Taking into consideration all the enormous difficulties of gerontological and geriatric research involving all branches of science and medicine, the following conditions appear to be necessary for a rapid advance towards a solution of this vital problem of humanity:

(1) Just as in the case of the splitting of the atom, co-operative research work of scientists and medical men of all civilized countries is necessary. With this aim in view, the Club for Research on Ageing has been established with branches already formed in England, U.S.A., France, Denmark,

Sweden, and Switzerland; branches in other countries are in a state of formation or, as we hope, will soon be established.

(2) Large funds must be available for financing gerontological research in all its manifold aspects. The grants, given for few years, will not tempt many research workers to become specialists in gerontology and geriatrics, since any clinical or experimental research scheme on ageing necessitates some years of careful work. For example, it takes about 2½ years to breed old rats before starting any experiments on them. Besides, the research worker has to think about his future and that of his family.

(3) The establishment, in each major country, of an Experimental and a Clinical Institute for Research on Ageing.

(4) The formation of a sufficient number of groups of gerontologists and geriatricians in each civilized country. Obviously points (2) and (3) are essential for this purpose.

(5) The continuation of the policy of interesting in gerontology different existing biological and medical laboratories and research hospitals so that they devote at least some of their efforts and time to research on ageing. Co-operation between scientific bodies and municipal hospitals and infirmaries for old people is most desirable, as the experience of the British Branch of the Club has shown in the case of co-operation with the London County Council. Long-term grants, of at least five years' duration, are necessary in these cases. Experience has also already shown that voluntary workers without remuneration, and "temporary gerontologists" (i.e., those who have agreed to do some gerontological research for a few years only), are often not to be counted upon for any length of time because of the call of their direct duties or their acceptance by them of permanent posts elsewhere.

Summary†

For the rapid advance of gerontology and geriatrics the following conditions are desirable: (1) Co-operative research work of scientists and medical research workers in civilized countries. (2) Large funds for financing this research. (3) Establishment of experimental and clinical Institutes for Research on Ageing in major countries. (4) The formation of groups of research workers in gerontology and geriatrics. (5) Large long-term grants to existing scientific and medical laboratories and research hospitals who will agree to stay in gerontological or geriatric research work.

BRITISH-SWISS MEDICAL CONFERENCE INTERNATIONAL MEETING AT BASLE

A British-Swiss medical conference, organized jointly by the Swiss Academy of Medical Sciences and the Royal Society of Medicine, was held during the week beginning Sept. 1. About 150 members of the medical profession, largely representative of the medical faculties of the universities, travelled from Great Britain to Basle, where they were received with the most generous hospitality by their Swiss hosts, who, to about the same number, attended the conference.

The opening meeting was held in the fine hall of the Natural History Museum and the other sessions in one of the theatres of the University. Twenty-four papers were read, fourteen of them by British authors, and the remainder by professors or directors of departments in the universities of Basle, Bern, Zurich, Lausanne, and Geneva. The great majority of the Swiss speakers delivered their papers in English, and for members of the audience who could not follow the language system of simultaneous interpretation was organized. The text of all the papers was published in a special number of the *Schweizerische Medizinische Wochenschrift* and a copy was presented to every visitor. Alike on the social and scientific side everything possible was done, under the guidance of Prof. G. G. Gigon, secretary-general of the Academy, to make the sojourn of the visitors in this historic and dignified city, untouched by war damage, pleasurable and stimulating.

† All statements in the summary have been approved by the conference of the British Branch of the Club for Research on Ageing as expressing the views of the conference, and have been adopted as resolutions by the conference.

* An address to the first conference of the British Branch of the Club for Research on Ageing, held on July 16, 1946, at the Imperial

Cultural Relations

The President of the Swiss Academy of Medical Sciences, Prof. C. WEGELIN, in welcoming the visitors, mentioned that an invitation had been sent to Mr. Winston Churchill, who was visiting Switzerland, to attend the opening ceremony. He was unable to do so, but sent his best wishes. They had greatly desired to see Mr. Churchill, said Prof. Wegelin, because of their admiration for the way in which he had stood like a rock against Nazi aggression. He referred to the long history of cultural relations between Great Britain and Switzerland. Such names as Harvey, Sydenham, and Jenner were honoured among the Swiss. During the war the Swiss had felt the liveliest sympathy with the British people in their sacrifices and had mourned especially the isolation of cultures. To help to bring that isolation to an end and to abate the psychological disturbances which the war had left behind was the aim at the back of their meeting.

The British Minister in Switzerland, Mr. P. M. SNOW, followed on the same lines. Switzerland and Great Britain were divided during the war, but it was a physical division only; spiritually they had never been divided. He mentioned the names of a number of men of science who had both British and Swiss affinities. LORD AMULREE attended to bring the blessing of the British Minister of Health and spoke of various directions of advance in social medicine, especially in respect of the problems of the care of the aged. The Swiss Minister in London, M. RUEGGER, a member of the Federal Council, Dr. ETTER, and a representative of the Basle civic authorities endorsed the welcome.

Finally the rector of the University, Prof. EDGAR BONJOUR, spoke of the close alliance of the Swiss and British medical professions. It belonged, he said, to the best traditions of Basle and of Switzerland to promote the international exchange of the treasures of culture. Basle stood at the intersecting point of important arteries of communication and on the frontier of old cultures. To re-establish internationalism in a world where so much had been destroyed was to her a task of capital importance. Heroin she adhered to the good old tradition of *Helvetia Mediatrix*.

"During the world war that has just terminated England has drawn support from her great prestige of earlier centuries. We in Switzerland felt for the fate of England with all our hearts, rejoicing in her victories with a gasp of relief. What made the greatest impression on us was the spiritual power which enabled England to triumph in the end. We admired the way in which, through many anxious years, the men of science and learning resisted all temptations to lose heart and never betrayed the mind."

The Task of Reconstruction

Mr. J. B. HUNTER, of King's College Hospital, acknowledged the welcome on behalf of the British visitors, and described the great tasks of reconstruction which now awaited the British universities. The health services of Great Britain, he said, were also in the process of reorganization, calling for much physical and mental readjustment, but it was hoped that as a result new facilities for research would come into being. The various Faculties of Medicine were sure that present difficulties would be overcome and that progress in the future would be as steady as in the past.

Dr. ALAN N. DRURY, for the British Organizing Committee, recounted the circumstances which gave rise to the conference. The first move was a letter by Prof. Gigon to Sir Henry Dale, who took the matter up with warm sympathy. Prof. J. H. DIBLE spoke on behalf of the scientific societies in Great Britain which had co-operated in the event. In an eloquent plea for the conception of the social and spiritual duty of medicine he referred to the contributions of the ordinary research worker and clinical observer. In the extension of knowledge it happened now and then that some genius constructed a viaduct or laid a long stretch of permanent way, but in the main progress came about through the steady plodding labour of innumerable workers.

First Scientific Session

After these allocations the scientific work of the conference opened with an address, delivered in German, by Sir HUGH CAIRNS on head injuries in the second world war. It was a

recapitulation of what has appeared under his name in the *British Medical Journal*. He illustrated the design of the crash helmet, which, he said, had reduced the number of head injuries and modified the effects of concussion. He claimed that crash helmets had reduced hospital admissions by 50%, fractured skulls by 75%, and the prolonged amnesias following injury by 66%. He stated that long bed-rest was not essential to the after-care of head injuries; a short bed-rest of a few days, together with graduated physical exercise and psychological treatment, was more effective. He also discussed surgical intervention in compound injuries of the anterior fossa of the skull.

This and a number of subsequent papers were discussed together at a special meeting under the chairmanship of Sir HENEAGE OGILVIE. Sir Hugh Cairns, in reply to questions, said that the weight of the crash helmet was 900 g., and it was quite comfortable to wear. He thought there was a case for making it compulsory for motor-cyclists.

In the afternoon, with Sir LEONARD PARSONS presiding, Prof. LUZIUS RUEDI, of Berne, discussed acoustic trauma, its origin and prevention. He divided acoustic trauma from the functional point of view into two groups: (1) noise trauma, together with trauma associated with certain blunt head injuries, and (2) explosion trauma; and he indicated the pathological grounds upon which the special place occupied by the latter could be supported. A number of experiments on the human and animal ear were described which led to certain new conceptions of the physics of the internal ear. The observations, he said, appeared to confirm the hypothesis that all natural sounds such as industrial noises or explosions had a broad frequency spectrum which in a cochlea gave rise to certain pairs of eddies. These opposing eddies changed direction at a range of frequency of 4,500 cycles per second, so that at that point the basal membrane was exposed to great tension which might result in permanent damage. He also demonstrated a new ear defender, an outer shell covering the whole ear and studded with tiny holes, thus forming a resonator whose resonating frequency was very much damped down. With this instrument, on a pistol shot the pressure amplitude was diminished by about 1:10. The protective function of the ear defender had been tested both on guinea-pigs and on human ears.

Circulatory Failure

The final paper of the session was given by Dr. JOHN McMICAL, of the British Postgraduate Medical School, who discussed circulatory failure. The failing human heart, he said, responded like the overloaded heart in Starling's heart-lung preparation. Mechanical reduction of venous pressure led to improvement in cardiac function. He stressed the importance of the pressure-reducing action of digitalis in bringing about improvement in cardiac output. In ordinary cases of heart failure the aim should be to bring down the venous pressure to normal as soon as possible. Within half an hour it was known what result was going to be obtained with digoxin, and if the venous pressure did not come down altogether to normal as a result of digoxin, theophyllin ("cardophyllin") should be given, and if these two measures were not enough, resort should be made to venesection. These procedures could be followed one after the other, and the clinical results were well worth while. The aim was to carry out all these measures if necessary in order to bring the venous pressure down, and the measures were quite safe and painless.

At the subsequent discussion meeting Dr. McMichael's paper called forth a considerable amount of comment. Asked why he used digoxin instead of strophanthin, and whether the one was superior to the other, Dr. McMichael said that he did not know why digoxin was used, but his chief at the British Postgraduate Medical School, Sir Francis Fraser, never used strophanthin, although it was introduced into therapeutics by his father, Sir Thomas Fraser, of Edinburgh. He had tried to find out why strophanthin was so much emphasized in American literature, and he learned that when Vaquez put digitalis on a frog heart it stopped in diastole, but when he used strophanthin it was arrested in systole; on that subtle difference it was supposed that strophanthin acted on the muscle, so that if an effect on the myocardium was desired, strophanthin was used. Dr. E. ROTHLIN said that the frog was not a good experimental animal; it reacted in the reverse way to the cat, and usually in

Switzerland, as in Great Britain and America, they standardized on the cat.

Stilboestrol

A crowded audience listened to an exposition by Prof. E. C. DODDS on oestrogens in cancer. He referred chiefly to the treatment of prostatic cancer by stilboestrol. The result of the introduction of oestrogens, he said, had been a widespread tendency to "dose" with stilboestrol everybody who had any type of cancer, but a careful examination of the claims showed in almost every case an absence of justification for the widespread use of this and its sister substances in the treatment of carcinoma in general. The interesting fact did appear, however, that in inoperable carcinoma of the breast some 5% of cases received a definite benefit, varying from a slight improvement in the local condition to a tendency of a fungating carcinoma to heal, and in a few cases to the disappearance of the lesion. But in the treatment of carcinoma of the prostate the results were clear-cut. The opinion of expert urologists of most countries was that such patients should be treated with stilboestrol, though even here it was in no sense a cure; it was a control, a means of palliation, lasting for varying lengths of time, in some cases for the whole five years over which the observation had extended, and sometimes only for six months.

In some later discussion on Prof. Dodds's communication Dr. J. McMICAL pointed out that the patient with cancer of the prostate very frequently had no very definite prostatic symptoms. He might arrive at hospital with symptoms due to secondary deposits, and an examination of the prostate by means of x rays might show calculi, which possibly co-existed with carcinoma. A diagnostic measure which had been suggested was the administration of testosterone, 50 mg. daily, upon which the acid phosphatase level, if it had not already risen, would steadily rise. In one patient the answer was clear: there was a steady rise of acid phosphatase level, which fell as soon as administration ceased, and this patient, after being given stilboestrol, was able to leave hospital. But in another case the response to testosterone injection was very irregular, falling while injections were continued, and rising to a peak after they were stopped. This patient also was put on stilboestrol, but went downhill quickly and died with massive secondaries about four months later. Sir HENEAGE OGILVIE said that he had the impression that the Americans were now preferring castration to stilboestrol.

The Kidney in Infancy

Prof. R. A. McCANCE, of Cambridge, discussed the physiology of the kidney in infancy. For some time after birth the kidney did not function as in adult life. The excretion of water was adequate for normal requirements, but defective by adult standards; the osmotic pressure of the infant urine was low, and only rose to adult levels when the serum became highly abnormal. The glomerular filtration rates in infancy appeared to vary with the hydration of the body, whereas in adults they were relatively constant, so that quite mild hydration in an infant was almost equivalent to acute renal failure, and, finally, urea and mineral clearances in infancy were very low. It was obvious, said Dr. McCance, that this work had great practical applications, because if the infant, newborn or in early infancy, was so incapable of regulating the constancy of the internal environment it was clearly for paediatricians to do their best to maintain, and if necessary to restore, such constancy in their patients. But no one could say how much water and how much salt must be given to the next dehydrated baby he was called upon to treat; such decisions could be made only at the bedside.

Sir LEONARD PARSONS said that this paper was important because it stressed an aspect of physiology which had received little study. The physiology of the newborn infant was different, just as its anatomy was different, from that of the older child or adult. In reply to a question by Prof. ROLF MEIER, Dr. McCance said that the adrenal cortex was extremely hypertrophied at birth, and he had often wondered whether the hormone excess secreted by the gland at that time might not be the cause of the oedema seen in premature babies, but he had no evidence to that effect.

Sympatheticotrophic Drug Action

A most interesting paper on the differentiation of sympatheticotrophic drug action was read by Prof. MEIER, who is the head

of the pharmacology department of Basle University. From an investigation of a large series of such compounds—phenyl ethylamines, phenylpropylamines, and others—he came to the conclusion that their type of action was identical in only a few cases; mostly there existed marked qualitative differences especially in blood-flow reaction. Instead of classifying substances generally, therefore, as "sympatheticotrophic drugs," their several effects throughout the system should be considered as differentiated with higher or lower specific affinity for some part of the sympathetic system.

Dr. E. ROTHLIN, of Basle, considered that what was needed was a real definition of sympatheticotrophic drugs. Adrenaline, the most effective product in the group under review, was a sympatheticotrophic drug; on intravenous injection there was a rise of blood pressure, but if the blood pressure rose 20 or 30 mm. Hg, it was counterbalanced by a parasympathetic action which, on the heart and vessels, was stronger than the direct action of adrenaline. If an intravenous injection of ephedrine were given the blood pressure rose much more than with adrenaline, but there was no parasympathetic action. There must be a very big difference between adrenaline and ephedrine, yet both were sympatheticotrophic. The question of classification badly wanted clearing up.

Pulmonary Tuberculosis and High Altitude

Dr. J. E. WOLF, of Davos, discussed the effect of altitude in the treatment of tuberculosis. High altitude—meaning heights of 4,000 to 6,000 ft. (1,200 m. to 1,800 m.)—exercised partly a stimulating and partly a sedative influence on the tuberculous patient. The increased power of resistance induced in tuberculous patients after a stay at a high altitude was partly due to a change in the vitamin metabolism.

Another Swiss tuberculosis expert, Prof. E. GRASSET, of Geneva, described some work on tuberculosis in virgin stock (a South African population). The moral of a long discourse was the usefulness, in view of the impossibility of controlling the bacteriological and epidemiological conditions of primary tuberculous infection, of the "pre-munition" method which substituted for the virulent, invading germ an avirulent one such as the B.C.G. With improvements such as the percutaneous inoculation method, "pre-munition" had entered a new and promising phase.

Amputations

Mr. GEORGE PERKINS, president of the British Orthopaedic Association, gave an exposition of amputation. Unless the surgeon could guarantee a stump which would satisfy the requirements of the limb-maker, he should plan to perform two operations—a provisional amputation, followed at a later date, when the requirements could be met, by a definitive amputation at a higher level. On Syme's amputation Mr. Perkins said that few would decry it when cleanly performed by the experienced surgeon. It was not a question of whether the Syme was a good or a bad amputation, but whether the results in the hands of the average surgeon justified recommending it as a suitable amputation for the "greenhorn." It was of no use relying on the good sense of the surgeon, because he did not know his limitations. The technique of the definitive operation which he described was based on two considerations: (1) amputations were of necessity performed by all manner of surgeons, so that there was much to be said for a simple technique applicable to all four main amputations, and (2) the technique chosen should conform to the wishes of the limb-fitting surgeon, who alone knew what sort of stump best stood up to the stress of limb wear. From the limb-fitting surgeon they learned that in the ideal stump the scar was not exposed to pressure and was not adherent, the skin was not infolded, there was no redundant soft tissue and no projecting spur of bone, the stump was not tender, and the wound had healed by first intention.

Sir HENEAGE OGILVIE said that the paper raised some controversial points. Most surgeons, he thought, if they themselves required an amputation would "pray that their friends would do a Syme before sending them to Roehampton." Mr. Perkins appeared to be of opinion that a "below-knee" was as good as a Syme and less trouble. But the Syme did not need a prosthesis. The below-knee amputation seemed to presuppose that the men would be for the rest of their lives under the care of the Government, which would supply them with whatever

MERSALYL B.D.H.

(Injection of Mersalyl B.P.)

The use of Mersalyl B.D.H. should constitute the primary treatment whenever it is necessary to induce prompt or prolonged diuresis. Supplementary treatment, where necessary, may be varied according to the individual needs of the patient. In cases in which there is cardiac involvement, digitalis may be given collaterally. Debilitated patients who may be unduly susceptible to toxic effects of mersalyl should be given Vitamin C B.D.H. to minimise toxicity and to augment the diuretic effect. Patients with liver involvement should be given Dehydrocholin B.D.H. in order to prevent hepatic injury by the mercury compound and, as in the case of vitamin C, to increase the diuretic effect. Further detail will be gladly supplied on request.

THE BRITISH DRUG HOUSES LTD. LONDON N.

Mrs J. E. 12

Two advances in Opiate Medication

DILAUDID

TRADE MARK dihydromorphinone BRAND

Improved Morphine Preparation

Whilst the analgesic power of "Dilaudid" is five times as great as morphine its hypnotic effect is considerably weaker. The euphoric element is largely subdued and addiction risk correspondingly lowered. Tolerance is improved, an increase of dosage rarely necessary. The effect on peristalsis is slight and much less persistent than with morphine.

DICODID

TRADE MARK dihydrocodeinone BRAND

Powerful Antitussive

Occupying a place midway between morphine and codeine, "Dicodid" exerts a selective influence on the cough centre. Better tolerated than morphine, it also interferes very much less with expectoration. Causes no constipation.

procedure was necessary. But the man on whom the Syme operation had been done, even if he went to the ends of the earth, could always make his own prosthesis. His own feeling was that the Syme operation, even if it meant re-amputation in seven or eight years, was the operation of choice for injuries in which that amount of foot could be saved.

Acclimatization to Heat

The subject of man in relation to his environment was taken by Dr. E. A. CARMICHAEL, of Queen Square Hospital, London, but he had time only to deal with tropical climates. When exposed to a hot environment men reacted differently according to their previous experience. The process of acclimatization or adjustment required from 4 to 7 days, by which time approximately 80% acclimatization had occurred. He emphasized the need for taking fluid in a hot environment. A man might lose as much as 10 litres of sweat a day, which meant 50 g. of salt. If replacement was restricted to fluid, without taking account of salt, there was a tendency to heat cramp. Recent work at Cambridge had shown that breakdown occurred at an earlier time and at a lower level for psychological than for physical efficiency. On the subject of clothing for the Tropics, he said that experiments with various garments had shown that a closely woven cotton fabric was more to be recommended than open-mesh poplins. A point to be considered also was the desirability of making people in the Tropics drink more than was actually necessary to alleviate thirst.

In reply to a question Dr. Carmichael said that in air-conditioning in the Tropics it was well not to reduce the temperature to the levels obtaining in a temperate climate.

Prof. McCANCE pointed out that large numbers of people in the Tropics were living in a state of dehydration. The only stimulus to make one drink was thirst, and in the Tropics water was lost so quickly that that stimulus was never quite sufficient to enable the individual to drink himself back to normal. This had not been appreciated by those who had to live and work in the Tropics and to handle men there. Sir Heneage Ogilvie said that this was also a great problem in desert warfare. The liability to shock was greater and the resistance to infection much less if little water was available. Sir P. MANSON-BAHR said that a queer aspect of the problem was the existence of some animals in Africa—antelopes and gazelles—which lived from one year's end to another without any water at all. There were also geographical questions to be considered. How was it that heat stroke was much more common in the Irak area than anywhere else—for instance, in western Libya—where the conditions were much the same?

Nutrition in Switzerland

Prof. ALFRED FLEISCH, of Lausanne, described the state of nutrition in Switzerland during the war. One of the tables he exhibited showed the total mortality and the mortality from certain intestinal diseases:

Annual Mortality per 100,000 inhabitants

	1934-38	1939-43	1944	1945
Total	1,154	1,136	1,200	1,160
Deaths due to digestive disorders ..	72	62	63	64
Deaths due to gastric and intestinal ulcer ..	7.5	8.3	9.7	10.0
Deaths due to appendicitis	12.5	9.4	7.2	—

During the last six years in Switzerland rationing had covered nearly all important food products. It had been well organized, with the minimum of "black market," and during the war years the amount of food had been diminished little by little to a level which was plainly below the theoretical minimum. The results suggested that the large amounts of calories, proteins, and fats formerly considered optimum in Switzerland, as in England and the United States, were not necessary. Instead of the 2,400 calories daily claimed by the League of Nations for adults not doing special manual work, 2,160 calories daily seemed sufficient. In particular the large quantities of fat consumed before the war were unnecessary and even injurious. For a long time paediatricians had admitted that somewhat scarce feeding was better than over-feeding, and this was as true for adults as for children.

Sir LEONARD PARSONS challenged this last statement; it was not true of British and American paediatricians. Certainly if a child was fed on a rather larger diet than normal it grew more quickly, and, bone formation not keeping pace, there might be some rickety tendency; but to say that a child was better on a starvation diet, or something approaching it, was not correct.

Prof. McCANCE said that it was interesting that Prof. Fleisch should have found seasonal variations in haemoglobin—a maximum in summer and autumn and a minimum in spring. There were also quite striking seasonal changes in the ability with which adults absorbed calcium—the majority absorbing it much better in summer than in winter. The reason was obscure, but it was not due to insufficiency of vitamin D. There was too great a disposition to regard the human being as "aseasonal."

Experimental Diabetes Mellitus

Prof. F. G. YOUNG, of University College, London, gave an account of experimental diabetes mellitus in depancreatized animals. It was almost certain that the human disease was not a single syndrome with one cause; it must consist of a number of different conditions arising from various causes, but with the majority of symptoms in common. The anterior pituitary gland almost certainly ranked as an extra-pancreatic factor of importance in a proportion of cases. Despite the extensive investigations since the classical work of von Mering and Minkowski, the causes of diabetes mellitus in all its forms were still unrevealed.

In the ensuing discussion it was mentioned that children born of diabetic mothers were often larger than children born of normal mothers, and this obtained even in children whose mothers did not develop diabetes until five or ten years after the child was born.

Another interesting paper was presented by Prof. A. VANNOTTI of Lausanne, on the adaptation of the human organism to effort, altitude, and to pathological oxygen deficiency. He said that to a prolonged deficiency of oxygen the organism reacted not only through a modification of respiratory and circulatory mechanisms, but also through reactions at the tissue level where the purpose was to facilitate the transport of capillary blood oxygen. He discussed a number of observations which, he said, demonstrated the clinical and other importance of the cellular system of biological catalysers, the insufficiency of which was able to exert unfavourable consequences upon the organism. Prof. Vannotti was highly complimented upon his paper by the British physiologists present. Any extended reference to the other papers must await a subsequent issue. They included an excursion into the therapeutic possibilities of the new discoveries in nuclear physics, by Dr. J. S. MITCHELL; a discussion on normal and defective fat absorption, by Prof. A. C. FRAZER; the chemotherapeutic control of malaria, by Prof. Hamilton FAIRLEY; the rhesus blood groups, by Dr. R. R. RACE; arterial injuries, by Mr. Mason BROWN; a paper on child health, by Prof. C. McNEIL; a demonstration by Sir Reginald WATSON-JONES on surgical rehabilitation, and Dr. Donald HUNTER's "popular lecture," delivered at Rheinfelden Spa, on industrial medicine in Great Britain. As the President of the Swiss Academy, Dr. Wegelin, said in closing the conference, the subjects taken had embraced the whole of medicine. They had not been confined to a few narrow specialisms. The difficulty was to bring so wide a range into focus. Dr. Wegelin added that if he were not an old and retired professor he would go to England as a student of medicine.

The names of many of the British visitors have been mentioned in the foregoing account. Others who were present included:

Dr. C. SHATTOCK, Prof. John McGrath, Prof. David Campbell, Prof. C. Bruce Perry, Prof. A. W. M. Ellis, Prof. John Cruickshank, Prof. J. Henry Biggart, Dr. Douglas McAlpine, Prof. L. P. Garrod, Prof. Sydney Smith, Dr. H. A. Clegg (*British Medical Journal*), Dr. G. H. Macnab, Dr. N. Howard-Jones, Sir John Fraser, Sir P. Manson-Bahr, Dr. S. Cochrane Shanks, and Dr. J. M. Graham.

The Swiss Academy paid a compliment to their English visitors by asking one of them to preside over each session, and the respective chairmen were Sir Leonard Parsons, Dr. R. A. McCance, Prof. R. St. A. Heathcote, Dr. Alan Drury, Sir Heneage Ogilvie, Dr. C. E. Newman, and Prof. A. St. G. Huggett.

At a conference banquet held at the Hotel Drei Könige, which was attended by the President of the Canton of Basle and other Swiss notabilities, Prof. WEGELIN, who presided, again expressed his pleasure in the occasion, and showed an appreciation of the medico-political situation in Britain when he said that the shackling of the free activities of medicine by the State was not to be tolerated. The Dean of the Medical Faculty of Basle, Prof. LUTZ, spoke in praise of the international commerce of medicine, and a general practitioner, Dr. OTTO LEUCH added a few words as representative of the Swiss Medical Federation, a small sister, he said, of the British Medical Association. Sir HENEAGE OGILVIE replied for the guests and offered their congratulations upon the splendid organization of the Conference.

Those attending the Conference learned with much regret that Mr. J. B. Hunter had been taken seriously ill after the opening sessions, and had been taken to a nursing home. On the final day of the Conference it was announced that he was going on as well as could be expected.

Correspondence

Postgraduate Education and the Health Service : Training the Specialist

SIR,—Those of us who hold that all is not well with the system of training of the future specialist in Great Britain will welcome Sir Francis Fraser's plain statement (Sept. 14, p. 354) that "the holding of a responsible hospital appointment does not of itself suffice," and his plea for a more positive training in which the working conditions have the setting of an intellectual background. Sir Francis goes on to suggest that these conditions are likely to be found only in the hospitals of the medical schools. But I would ask (and I do not ask Sir Francis, for he knows the answer as well as I do), in how many teaching hospitals, general and special, in Great Britain to-day can evidence be found of purposive training? In how many hospitals are there libraries accessible to the wards or departmental libraries within units, and as part of the regular weekly routine, hospital, departmental, or "trainee" conferences? Again, in how many hospitals is sustained research a feature of the period of training? And finally, how many trainees go out into the world indoctrinated with the faith that they are debtors both to their profession and to medical science?

In arrangements for the training of the future specialist we have lagged behind the U.S.A. and Canada for some considerable time. The experiences of a recent visit to the North American continent (June-July, 1946) have once more reminded me of the great defects in our own system—or of the lack of

In the United States to-day, among the chiefs of the various clinical services in the great medical centres, there is a sense of responsibility in this matter; for there is the same need for a widely distributed specialist service in North America as in Great Britain. It was to me a stimulating and inspiring experience to enjoy the keen atmosphere of this post-war training drive in all too brief glimpses of such functions as surgical conferences at the Massachusetts General Hospital; the fortnightly tea meeting of residents, research fellows, and staff in the surgical laboratory of the Harvard Medical School, with the gallant Elliott Cutler in the chair; the weekly residents' and fellows' conference at the Hospital for Special Surgery in New York; and of the purposive training of the young surgeon in the great Toronto school of surgery directed by W. E. Gallie. These are a few examples of what can be found in almost every hospital of high repute in the United States and Canada.

If the essential working conditions and intellectual background of this period of hospital training for a specialist career, as set out by Sir Francis Fraser, are to be established in our teaching and non-teaching key hospitals, far-reaching reforms will be needed in the pattern of hospital staffing. It is clear that these standards must become part of the policy of the new Regional Boards. But Regional Boards will need instruc-

tion and advice. Meanwhile, a move is required from two sources: on the one hand the teaching hospitals, or more specifically their senior staffs, and on the other hand the Royal Colleges, stimulated by the specialist associations which have already enunciated progressive views on this subject. The universities also have their part to play by demanding evidence of such a standard of training before they recognize an individual as a clinical teacher.—I am, etc.,

Manchester.

HARRY PLATT.

Further Education of General Practitioners

SIR,—To those who are particularly keen on postgraduate medical education, irrespective of the proposed National Health Service, the lecture by Sir Francis Fraser in your current Educational Number (Sept. 14) is concise, interesting, and most stimulating. The scheme outlined by him on "Further Education for General Practitioners" should definitely assist in the "breaking down of the barriers to the exchange of knowledge and experiences and frequent contact with centres of teaching and research . . . should improve the standard of medical practice." More important still in my opinion "it will increase also the confidence of the medical profession in their ability to perform their high calling and give them cause for pride and happiness [my italics] in their chosen career." Please excuse extensive quotations from his lecture. It is such an important article that reprints of it should (if possible) be sent to every medical man and woman—whether G.P. or specialist. The latter would learn very much from it in the assurance and encouragement they could give to the "more enlightened and progressive members of the profession." Hospital authorities, too, would gain by a serious study of its contents.

Shortly before the war—in July, 1939—I was very fortunate in that I was able to attend an intensive refresher course of 2 weeks at Oxford, under the auspices of the Ministry of Health. I can vouch for the extreme usefulness of that particular course and I returned to my general practice, much stimulated and suffering in no way from "mental indigestion." It was very well organized. It was a happy and useful fortnight in a most congenial and learned atmosphere. Therefore it is with great pleasure that I note that the Ministry of Health is now contemplating the reintroduction of such intensive courses in general medicine and on some approved specialized subject, in 1947. I agree with Sir Francis that "now is the time to plan, and it is the time also to start boldly."

With regard to his first suggestion for the furtherance of the education of the G.P., viz., "Clinical assistantships at nearby hospitals," perhaps the hospital authorities and the powers that be would take due note of this and also of the method adopted at some hospitals as mentioned by the lecturer—e.g., at New castle-upon-Tyne. Perhaps when the demand for postgraduate instruction for demobilized doctors declines (? in 1947) the hospital authorities will open their portals to the interested G.P.—I am, etc.,

Leeds.

HARRY SUGARÉ.

Selection of Medical Students

SIR,—Light-hearted disregard of appropriate randomization is a little shocking in an article wielding the prestige of statistical methods, such as that by Mr. J. S. Wilkie on the selection test for medical students (Sept. 14, p. 367).

Questions 1 and 2 in the test are looked at askance because the score of the first-year candidates averages nearly 10% higher than the score of the second-year candidates, a whimsical possibility being suggested to account for so curious a result. In fact, the separate batches of first- and second-year papers were assessed at different times, the examiner was instructed to allow for the expected difference of standard in first- and second-year candidates, due to difference in age and experience, and he was further instructed to widen this difference in standard because the proportion of first-year applicants to be admitted was much higher than the proportion of second-year candidates to be admitted. Imagine the examiner's surprise and delight in achieving his intention, as shown by Mr. Wilkie's figures, and his bewilderment at Mr. Wilkie's attempt to explain them as an odd property of the candidates. Question 1 involves subjective and objective observation of superficial physiological changes in the candidate and her friends as a result of running. Mr. Wilkie emphasizes the exceptionally low correlation

between the marks in this question and those in the paper as a whole which predominantly involved general knowledge with its current connotation of somewhat academic erudition. The relative importance of tests of keenness of personal observation and of academic prowess can, of course, not be decided by correlation between them but only by correlation with subsequent success in medical practice. One might guess that both, however independent of each other, had some relevance in such a test.

Any criticism of the second half of Mr. Wilkie's article in so far as it detracts from the important conclusions he draws in the first half, namely that assuming that a general knowledge paper tests relevant qualities in intending medical students, then it is at least as reliable and much more economical of examiners' time to set questions in questionnaire form. One hopes that the general knowledge test will soon be compared with an intelligence test, and with other aptitude tests, in relation to success in choosing medical students, despite the difficulty and slowness of validation.—I am, etc.,

London, W.C.1.

F. R. WINTON.

Physiology of Vision

SIR,—Prof. Burridge takes me to task for having failed to point out to your readers the fact that Prof. Granit's work confirms his own views on the nature of colour vision which were first made public in his book, *A New Physiology of Sensation*.

I should like to point out to Prof. Burridge that in fact this work confirms the far earlier views of Prof. Wundt, published in 1893 (*Grundzüge d. physiol. Psychologie*, 1, 535). Very briefly, Wundt's theory was that two different mechanisms are put into operation when light is incident on the retina: (a) chromatic, and (b) achromatic. The former consists of many sharply defined receptors, which vary in their relative activity according to the spectral composition of the stimulus which is applied to them. The latter mechanism, on the other hand, is the same for all parts of the spectrum, except that a maximum effect is produced by the yellow-green, and that there is a gradual decrease in effect as the red and violet ends of the spectrum are approached. The resemblances between this theory and Prof. Granit's discoveries on the mammalian retina are very striking, for whereas Wundt's chromatic mechanism is well represented by Granit's seven "modulators," his achromatic mechanism finds its counterpart in Granit's "dominators."

Under these circumstances, I feel it is unnecessary to refer to other people who may subsequently have had the same idea.

Recently I have obtained some confirmation of the view that Wundt's theory applies to human vision. Using a micro-stimulation apparatus, by means of which very narrow rays of light can be applied to the fovea, it has been found that there are eight different fixation-points for rays of different wavelength. These lie within what may be called "areas of high visual acuity." Thus, when we want to see the detail of a red object, it is this area for red light which is utilized. Several other pieces of evidence are also available, confirming the same idea.

The present position can be summarized, I think, as follows: that, so far as can be seen at present, Wundt's polychromatic theory is at least as likely as the trichromatic theory of Thomas Young, which has served us so well and has been so prolific in stimulating human invention, since colour-printing, technicolour, and various other methods of three-colour reproduction and measurement have been derived directly from it.—I am, etc.,

London, E.C.1.

H. HARTRIDGE.

Migraine and the Sympathetic Nervous Pathways

SIR,—Mr. R. G. Rowbotham's article on "Migraine and the Sympathetic Nervous Pathways" (Sept. 7, p. 319) raises several points about which I am not quite clear. In the first place if we are to ascribe the cause of migraine to dysrhythmic impulses from the hypothalamus, which in turn is reacting excessively to stimuli having their origin in the blood or higher nervous centres, then the fact that the headache of migraine is essentially unilateral would mean that the hypothalamic imbalance was asymmetrical, or even unilateral, itself. Yet the postulated blood stimulus is presumably bilateral. Mr. Rowbotham would ascribe the beneficial effects of the operation to the interference

with the ascending sympathetic pathway from the upper thoracic cord. However, he also divides the external carotid artery at the same time. It is a well-known clinical fact that some migrainous headaches will respond to some degree to digital pressure over the carotid, superficial temporal, or other vessel, and an alternative explanation of the operative results might be that the external carotid was now ligated. Further, although the pain of the migrainous headache is now believed to have its origin in an abnormal dilatation of the dural and extracranial branches of the external carotid, yet in addition the internal carotid, via the meningeal and superficial frontal vessels, also supplies branches to the dura. This fact might explain the persistence of the pain, to a milder degree, after ligation of the external carotid. Finally, I should like to make it clear that it is not with the fundamental postulate that I disagree, but with the explanation offered for the beneficial effects of the operation—effects which might be due to the ligation of the external carotid alone.—I am, etc.,

London, W.14.

DAVID P. NICHOLSON.

Disability from Dust Diseases

SIR,—Your leading article on "Assessment of Disability in Dust Diseases of the Lung" (Aug. 31, p. 301) is of considerable interest to those of us practising in mining areas, and while we have received some new information, we feel there are some certain points that we cannot allow to go unchallenged. In your article you state: "difficulty of the assessment of disability is still there, and at present it is decided largely by radiographical appearances. This method is not satisfactory because it is impossible to differentiate between nodulation caused by iron oxide in the siderosis of arc welders and that shown by the fibrous nodules of silicosis." Surely you cannot seriously give this as a reason that radiographical appearances are not satisfactory; and if so, can we take it that the same applies to a fracture, as the radiologist cannot state whether the fracture is due to direct or indirect violence? Must we therefore cease to use the x ray for diagnosis of fracture? The fact that the reticulation in lungs of arc welders, South Wales colliery miners, and workers in iron foundries are essentially similar surely does not preclude x ray in the diagnosis of pneumoconiosis in any of these workmen.

While it may be true as you state that the men with iron oxide in their lungs suffer little or no disability, it is certainly not true that miners of the South Wales anthracite area suffered "little or no disability due to the presence of reticulation in their lungs." If the reticulation is coarse or dense, then there certainly is disability present among these workmen. We agree that there has been an increase of the number of men certified by the Board, not as "totally" but as "partially," disabled. This is not due to the difficulty of assessing disability, but is due to the fact that the disease has been recognized as disabling at an earlier stage. Hart and Aslett are to be congratulated in suggesting the inclusion of reticulation as a compensatable disease. We cannot agree that "many men with reticulation who are not disabled are obtaining disablement certificates," and we should be pleased to have your authority for this assertion. While we think the members of the Silicosis Board in this area would be the very last to claim infallibility, and while we are prepared to admit that some very few men with early reticulation suffer little or no disability, we are not prepared to allow to go unchallenged "that there is no doubt that many men with reticulation who are not disabled are obtaining disablement certificates." We have not found that the Board make partial awards without good reason.

In your summing up, we quite agree that physical examination is necessary, but reticulation (coarse) and nodulation do in our opinion mean that the patient is disabled. It would seem to us that research in this matter is being carried out at the wrong end of the stick, and while any method by which pneumoconiosis in miners can be easily and quickly diagnosed and the correct disability determined would be welcomed, we were always under the impression that preventive medicine was the present teaching in medical schools and not "locking the stable door after the horse has been stolen." In other words, compulsory examination of all mine workers at stated periods—both physical and with the aid of x rays unless x rays can be specially supplanted by a more definite and less expensive method. The crux of the matter is that the problem is primarily

a mining one, and secondarily a medical one. Over a period of some twenty years, when one of us was totally occupied by x-ray examination of miners' lungs, we were frequently struck by the number of men who, although working side by side with cases of silicosis later proved by necropsy, showed only very early evidence of pneumoconiosis. Is there some missing factor "X" which renders one man more liable to the disease than another? If there is, the finding of it and not the awarding of compensation when the workman is no longer able to follow any occupation would seem to us to be of prime importance.

Quoting again from your first paragraph "... diseases resulting from the inhalation of siliceous matter. The latter produces a fibrous reaction." Surely there can be no question that a widespread fibrosis of lung tissue, as is seen in these cases, must result in impaired lung function and therefore in disability. Furthermore, your leader states that "even if tuberculosis is not a complicating factor the lung is still gradually destroyed." This is surely good reason for removal of men with well-marked reticulation from the dust risk—which practice we invariably carry out. The questions of disability and compensation are later decided by the Silicosis Board with, in our opinion, a high degree of reliability, and yet they use no complex biochemical tests such as you suggest, but one means of assessing disability which you have apparently overlooked, namely, sound judgment based on clinical experience.—We are, etc.,

ARCHIBALD HARPER.
J. MANSEL MORGAN.

Ammanford, Carmarthenshire.

Facial Palsy Accompanying Acute Mastoiditis

SIR,—I was interested in Dr. Kenneth R. Ogilvie's article on the above subject (Aug. 24, p. 263). It is often assumed that facial palsy is indicative of an affection of the inner ear or the meninges. Dr. Ogilvie's cases show that it may indeed be only one of the signs of acute mastoiditis. May I add that facial palsy may also be one of the first signs of a simple acute otitis media, whether catarrhal or suppurative in origin? Every otologist has seen them; I personally have records of six such cases within the last few years.

What is the explanation of a facial palsy, both in simple acute mastoiditis and otitis media? How is it possible for the facial nerve, being tucked away in a bony canal, to be involved in a simple affection of the middle ear with or without extension into the antrum and mastoid process? Is it that in these cases the bony canal surrounding the facial nerve is either totally missing or that there is a dehiscence in the canal? These conditions are well known to anatomists. If this were the correct explanation one could well imagine that the facial nerve, being covered only by a mucous membrane, would participate in any inflammation of the latter. The facial palsy in these cases would therefore be due to a transitory neuritis of the nerve caused by extension of the infection. It would be interesting to hear the views of other otologists on this interesting condition.—I am, etc.,

London, W.1.

ARTHUR MILLER.

Folic Acid for Nutritional Oedema

SIR,—In your leader on "Malignant Malnutrition" (June 22, p. 958) you suggested that folic acid might possibly be of use in the treatment of nutritional oedema. We have employed folic acid (synthetic *L. casei* liver factor) in one case and found that the oedema disappeared in 7 days. The patient, a Bantu child 1 year old and weighing 13 lb., weighed 10 lb. after 5 days' treatment with folic acid.

The use of folic acid was originally suggested by one of us (L.G.) as the outcome of an investigation carried out by P. Fleming, H. D. Barnes, and ourselves during 1944-5, on the treatment of nutritional oedema with a papaic liver digest. It was felt that the oedema vanished, not as a result of added vitamins but through the action of some "anti-oedema" factor. No child ever improved, nor was in a position to absorb from the gut, until the oedema had begun to disappear.

Further cases are in process of being treated with synthetic folic acid, kindly supplied by Lederle Laboratories, New York, to whom our thanks are due.—We are, etc.,

S. SELBY.
L. GOLBERG.

South African Institute for Medical Research,
Johannesburg.

Health Service Bill

SIR,—Dr. C. E. S. Flemming is unfair to Dr. Dain in accusing him (Sept. 14, p. 399) of lack of logic and of using statement difficult to substantiate, for he quotes in support of his criticism Mr. Key's remark that every doctor will be free to enter the Service. Now Mr. Key had previously described this claim as impossible and impertinent, and at the time of Dr. Dain's speech nothing had been said to alter that view. Dr. Flemming falls victim to his own complaint. It is not easy to substantiate his claim that the new method of getting a practice has been shown to be a real improvement on the old or that the result of payment by part salary will not be a new form of control over the general practitioner. All this depends on the nature of the regulations made by the Minister. His policy must not be confused with that of his friends, upon whose support he depends, and whose policy still demands a "national, full-time, salaried, pensionable service."

Few Ministers and no Governments feel bound to honour the promises or intentions of their predecessors. On Mr. Bevan's ability to remain at his post and to continue to control the policy of his party depends the realization of Dr. Flemming's hope that much that we do not like in the new Service will in time be regarded with satisfaction. Surely our recent treatment over the Spens Report and the capitation fee tends to show not that the Minister is unwilling but that he is unable to control his friends and advisers. To bargain for delay and hope for the best is little more than a policy of despair, which will not bring us towards contentment but may lead us elsewhere by a way paved with Mr. Bevan's good intentions.—I am, etc.,

Warminster.

R. W. GRAHAM-CAMPBELL.

SIR,—I congratulate Dr. H. M. R. Waddell on his admirable letter (Sept. 7, p. 340). He gives expression to a dissatisfaction which I have so far endured in silence. To many of us it must be impossible to be strongly for or against central versus regional administration and Government ownership of hospitals when we have not experienced them. We cannot be expected to wax indignant about the interference in the doctor-patient relationship under National Health Insurance, a relationship worn so frail by inadequate payment for large numbers of chronics and hypochondriacs that we care not who leaves our panel as long as new arrivals replace them. Nor can we be very exercised about our right to enter a new and similar service when doubtless the Government will be only too glad to accept all comers in view of the shortage of doctors.

What interests me most vitally is: (1) whether or not I shall have to work longer hours for less money; (2) the pension of a middle-aged practitioner now entering the Service will get on retirement; (3) the basis of compensation for practices bought since 1939; (4) whether I can retire when I wish and receive the compensation for my appropriated practice.

From Mr. Bevan's refusal to accept the recommendation of his own Spens Committee on the capitation fee I can only draw a sinister conclusion, unless he intends that we shall really be Civil Servants with a fixed-hour day of limited duration and absolute freedom from responsibility outside those hours. Yet the sudden incorporation of the whole population in the new health scheme implies that the existing force of doctors must undertake more work until its numbers are increased—an ironic result, since its detractors condemn as an evil of the Panel system the tendency for doctors to take on more patients than they should in order to augment their income.

This Government came into power as the champion of the oppressed worker. What it and the public do understand are hours and wages. Let us talk to them in their own language and command their appreciation and respect.—I am, etc.,

Bournemouth.

A. R. THATCHER.

SIR,—It is possible that, on balance and in the long run the National Health Service will prove beneficial to hospital practice and detrimental to general practice. How does the B.M.A. suggest that consultants should vote in its referendum assuming (as is not the case) that sufficient information lies before them upon which to form an opinion?—I am, etc.,

London, W.1.

ROYDON PEACOCK.

Two-grade Medical Service under the Act

SIR,—It is a truism to-day that medical man-power is inadequate for the decent care of our population. All parties are pledged to make an equal distribution of what is available regardless of the patient's finances. When a vital commodity, e.g., milk, is in short supply but is rationed equally among us we are satisfied. If, for comparison, we express medical services in terms of doctor-hours, which is mainly what they consist of, then the Act falls short of the objective. The Bill will mean, so to speak, skim milk for the masses while the cream will go to the private patient; and more patients who can pay will resort increasingly to doctors privately and so procure less meagre doctor-hours. It will be galling for the man-in-the-street to be taxed for what amounts to skim medical milk for the next ten years.

Under the Act payment will be at a fixed rate and virtually automatic owing to the scarcity of doctors. This stultifies effort, for the average doctor is only human and puts forth the extra effort when there is corresponding reward. Half the good the patient gets out of his doctor is in service of an intangible kind not susceptible of supervision; and the amount of care he gives, not the fittings and style of his surgery, is what counts most. When patients are too numerous for decent handling, then those among his clientèle who are willing to pay will, by reason of the private contract, command that personal touch which we all covet. The Act will perpetuate the present *versus* private division of medical service which has led to the disrepute of the profession. The distinction is disconcerting and demoralizing to the young doctor who at hospital learns how to *extinguish* disease and not to *distinguish* between the victims of it. That is the mainspring of professional life, and proficiency has been furthered by an atmosphere of competition which fosters ambition, enterprise, and effort. The guardians of health cannot afford to ignore healthy rivalry which bred the renowned English family doctor; and loyalty to the profession forbids acquiescence in conditions calculated to lower our standard. Parliament may be satisfied, but we shall not be until medical service of one grade, equal in quality and quantity, is meted out to all according to the disease, not the purse, of the patient. To attain service of the best quality a competitive element must be conspicuous in the scheme. In these vital principles the Bill largely fails, but voicing them in the *Journal* will show future generations the feeling of some of our profession in these matters.—I am, etc.,

Clifton, Bristol.

A. WILFRID ADAMS.

Early Treatment of Ocular Defects

SIR,—Dr. M. C. Mason's letter shows how important it is that children who begin to squint or have signs of any eye trouble should be seen *at once* by an eye surgeon (Sept. 7, p. 338). When I first commenced as an eye surgeon some thirty-odd years ago, I well remember the parents of squinting children objecting to the school authorities saying their children should have treatment, and that as a higher power had made them like that they would allow no treatment. That was in an age when employees were afraid to wear glasses because they thought they would be thought old and lose their work; yet six years ago I saw three American sailors together and two were wearing glasses.

I noticed when examining recruits for the 1914-18 war that short-sighted young ladies kept their glasses in their handbags; the men, however, wore theirs. At the clinics at which I work there is nowadays no objection on the part of the parents or children to any form of treatment, and although the districts from which the children come vary greatly, I find the children equally keen to do anything to get rid of a squint or to remedy any other defect. In the case of squinters they want to look like their companions; for a girl it is a tragedy, as it lessens her matrimonial chances; and in either sex it may prevent its owner from getting employment. Again, children are not very kind about another person's defects, and it is difficult to hide a squinting eye—the most successful instance that I can think of being one of our lecturers, who wore a monocle in his left eye, which so fascinated us students that we almost forgot that the right eye turned in.

Well, an operation will at any time of life put a non-paralytic squint straight, which is all that the patients or their

parents worry about, *but* it does not make the eye that squinted see. Many of these eyes only have a tenth of full vision even if the appropriate glass is worn to correct the refractive error, while they are nearly useless for fine near work unless they have been properly trained. Unfortunately the last two wars have produced many instances of good eyes being lost or damaged, the owner being left with an almost useless squinting eye to carry on with. In 1935 (*Return of Sight in an Amblyopic Eye. Journal*, 1935, 2, 317) I showed how these amblyopic eyes could be trained to see; and in my clinics, where the proportion of squints is fairly high, I am much struck by the fact that we have a large number of cured cases that report regularly who started treatment at the age of five and have had squints of half a right angle cured by correcting almost all of the optical defect and covering up the good eye, thus making the child use its bad eye three or four hours daily. These children had even the smallest amounts of astigmatism corrected by my predecessor, Mr. A. E. A. Loosely, with the most scrupulous care.

Dr. Aston Key has a letter also in the column adjacent to Dr. Mason's. We find we get children with migrainous headaches caused by quite small visual defects who can see all the letters in the tests, and who gladly come back for replacements if they break or lose their glasses. This vast change in public opinion has been brought about in less than a generation by reason of the good results obtained and the spread of knowledge among the public.—I am, etc.,

London, W.1.

SYDNEY TIBBLES.

Sir Almroth Wright and Anti-typhoid Inoculation

SIR,—I happened to be a surgeon-on-probation at Netley in the year 1897 and remember the points made by Dr. Leonard Colebrook very well. A man called Marshbanks and I were both vaccinated by Wright to test out the dose of his anti-typhoid vaccine that summer, and very sick we both were, especially Marshbanks, after the inoculation. I have always attributed my almost miraculous immunity to the germ, when a year afterwards I had charge of a big camp of typhoid cases of the worst sort at Darmali in the Sudan, to my fortunate inoculation at Sir Almroth's hands. Leishman, as reported by Colebrook, arrived from India and was attached to Wright's laboratory at about that time. He was quite out of it as regards the initiation of the anti-typhoid vaccine but became intensely interested in it and in all the work that Wright was doing in subsequent months. At that time or a little later he invented his method of working out the phagocytic index, a method later modified by Wright to be the opsonic index, with which everyone is familiar.

After the transfer of the R.A.M.C. headquarters from Netley to London, Wright's interests in the immediate problems of anti-typhoid vaccine, though keen, were for the time being less great than Leishman's, who, as the professor of pathology at the R.A.M.C. College, was obviously the right man in the right place for the continuous work that went on at the vaccine between the South African and the 1914-18 wars—an effort in which Harrison, Grattan, Webb, Kennedy, and myself were all interested, as his assistants. But I feel sure that of all men Leishman was the last who would have claimed to be the originator of the anti-typhoid vaccine which was actually in hand and very far advanced at the time of his return from India.—I am, etc.,

S. LYLE CUMMINS.

Shock Treatment of Bronchial Asthma

SIR,—Subsequent to my letter (June 1, p. 849) and that of Dr. Bowman Edgar (July 20, p. 101) I would like to clarify certain points omitted in my short letter. In full agreement with Dr. E. M. Fraenkel (Aug. 3, p. 174) and Dr. E. S. Fennell (Aug. 24, p. 275) I wish to point out, as I have done elsewhere, that the *B. coli* shock treatment is neither the only cure for asthma nor the cure for every asthmatic. I always carry out an investigation of the nose and throat and other possible causes, according to the history of each individual patient. For instance, an asthma attack brought on usually by a head cold could indicate an infection of the sinuses. If this or any other organic cause cannot be found, or if after the removal of one the asthma persists, and if also

no specific allergen (outside the body) can be found by means of skin tests, etc., then the "pyrifer" shock treatment—as an "unspecific" measure—is indicated.

I would not use shock therapy in cases of chronic nephritis, auricular fibrillation, coronary sclerosis with clinical manifestations, severe hypertension, advanced age, decompensated heart, pulmonary tuberculosis, and pregnancy. On the other hand, the usual cardiac enlargement—with dyspnoea, occasional cyanosis, and emphysema—so frequently met with in asthmatics, is no contraindication.

It is, of course, left to every practitioner's discretion to judge for himself and withhold the therapy where he thinks that any intercurrent febrile illness (as demonstrated by the reaction) would be dangerous. I have used "pyrifer" for the past ten years in a fairly large number of cases and have never had any unduly severe reaction which would have caused me anxiety as far as dosage is concerned. I may mention that I give children under ten about half the amount for adults. I always use "pyrifer" in the free interval between and not during the attacks, and visit my patients about 4 hours after the injection to watch the reaction.—I am, etc.,

Spennymoor, Co. Durham.

Royal College of Physicians of London

SIR,—The recent letter in the *Journal* (Aug. 31, p. 313) has focused attention once more on the statutes, bye-laws, and regulations of the Royal College of Physicians and the justifiable discontent which they arouse. As is well known, the present regulations do not allow Members to take any part in the running of the College. In fact, they are specifically debarred from doing so under Bye-law CXVIII, which says: "... they shall not be entitled to any share in the government, or to attend or vote at General Meetings of the Corporation." Surely this state of affairs is quite out of date, and in view of the great changes now taking place the time is ripe for the College to broaden its representation with a view to ensuring that Members obtain a voice in its counsels and deliberations on common-sense, democratic lines.

Our College instead of remaining a mere academic institution should become a dynamic force, capable of exercising a profound influence for good on various medical, social, and educational problems confronting us and pressing urgently for solution. The first step in this desirable aim must be the provision of facilities for adequate representation by the Members, who should be given every encouragement to form their own standing committee, etc., and take an active part in the management of the College. Obviously one of the important tasks of any newly elected committee should be to go into the question of the revision of the existing regulations concerning the election of Fellows.—We are, etc.,

C. ANDERSON.

Proposed Ex-Serviceman's Committee

SIR,—I have received many letters strongly approving my suggestion for the formation of an Ex-Serviceman's Committee of the B.M.A., and if I may trespass further on your space wish to suggest as a basis for discussion the form such a committee might take.

- (1) Specialists, 4 } All ex-Servicemen (Temporary Officers).
G.P.s, 5 }
Retired Regular Officer, 1.
Ex officio, one member of Council.
Secretary, an official of the B.M.A. staff.
- (2) Chairman to be elected by the committee and to be *ex officio* member of Council.
- (3) The retired regular officer would act usefully in an advisory capacity, and for liaison purposes should preferably be a member of the Naval and Military Committee.
- (4) The terms of reference should be: "To consider all matters concerning the problems confronting ex-temporary medical officers of the Services and to report to Council concerning their deliberations and recommendations."—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

Obituary

G. DOUGLAS GRAY, C.B.E., M.D.

It is with sorrow that we report the passing of George Douglas Gray, C.B.E., M.D., of Dalkeith, Scotland, and with pride that we here briefly record a remarkable career.

At 15, George Gray matriculated with honours, but finding that Edinburgh University was not prepared to enrol a boy of that age to enter as a medical student he falsified his age, adding a sufficient number of years to qualify for entry. It was not to be the only time that he disremembered his age. At the outbreak of the 1914 war Gray removed the requisite number of years to allow him to go to France. Having graduated M.D. (with honours) soon after his 21st birthday, he became assistant to the late Dr. Murray of Leith. After other assistantships in England he went to British Central Africa under the aegis of the Foreign Office in 1894, and was appointed Principal Medical Officer of a district the size of Scotland. There he battled successfully with the scourges of blackwater fever, dysentery, malaria, and all the ills that beset the white man pioneering in, and ill-adjusted to, an unknown "Darkest Africa." After six years of experience this young doctor established a laboratory for experiment, and for the development of tropical medicine, at Zomba on the Zambesi.

During the South African War Dr. Gray served with the King's African Rifles, and in 1901 was one of the exhausted band of half-dying men who staggered back from the relief of Kumassi. It was during the S.A. campaign he met his future wife, Lucy Harrison, a nurse who had volunteered to serve up-country, in circumstances that would have quelled the ardour of any young woman less wholeheartedly dedicated to a career of healing. Between them, they worked a wide field, his doctoring backed up by her nursing. Lucy Harrison was awarded the R.R.C. In 1902 they were married in England. Immediately on their return to Africa the Foreign Office appointed Dr. Gray to be Principal Medical Officer and Physician on H.B.M. Minister's Staff in Peking, China. Gray relieved Dr. Wordsworth Poole, who had lately died. He found a legation and a Peking slowly recovering from the effects of the Boxer Rebellion siege. He also found the embryo of a hospital, started by Dr. Poole, far outside the city walls in a courtyarded Chinese house for Chinese sick. This he organized and developed until it became something akin to a flourishing cottage hospital, staffed by Chinese doctors and nurses trained by himself, where he performed an average of 20 major operations a week. It was typical of his robust approach to life in general, and his work in particular, that he never begged for money for his hospital. He supported it largely by his own earnings, and when he left Peking for France in 1915 he wrote the songs and music for a pierrot show and with the proceeds endowed the hospital with a handsome carry-on even against his return.

In 1906, on the outbreak of pneumonic plague in Manchuria, he again, with an instinctive sense of fitness, knew that the problem must be faced by the Chinese themselves, but that he, with his British Foreign Office backing, could guide the gigantic task of plague suppression and restriction. He therefore initiated the appointment by the Empress Dowager of the then foreign secretary, Saoke Alfred Sze, to the presidency of the committee for combating the epidemic, and enlisted the services of medical experts on plague, irrespective of nationality and creed, and with them not only fought and overcame the pneumonic plague but collected research information which proved invaluable when later outbreaks threatened. 1915 saw Gray in France in the R.A.M.C. organizing and running the 2,400-bed hospital for the Chinese labour battalions. For this work he was three times mentioned in dispatches.

In 1929 he "retired"—we put the word in inverted commas for it has but academic meaning when applied to the career of one whose energies and activities were boundless. Having spent some years travelling round the world as a ship's surgeon he returned to Scotland and immediately identified himself with work connected with China. Gray championed the cause of the Chinese student in this country. He found that with the outbreak of China's war with Japan, many students were cut off from home supplies, and were, through no fault of their

own, well-nigh destitute—unable to return home, unable to continue their studies for lack of money. Gray saw to it that they received an allowance from the Boxer Indemnity Fund—again he permitted no question of charity or dependence to creep up. When the 1939 war came George Gray, at 70, threw himself into a multiplicity of activities, organizing and training the Dalkeith Home Guard; then combining the chairmanship of a recruiting board in Edinburgh with almost nightly lectures as first aid to units of the Army and Home Guard in the district. It was this intensive activity that brought on his collapse in 1943, and the stroke which paralysed his right hand. Even then he was not beaten, and, having taught himself to write with his left hand, continued to review books for the *British Medical Journal* and other publications.

It was the intention of the present writer to give a short summary of George Gray's career and leave space for an appreciation of his character, but a life so crowded with sheer going cannot be compressed into a few sentences, and there is left but little room to sum up a character of such unusual and sterling worth as Dr. Gray's. Dogged perseverance, humour that brought him lifelong friendships for his "entertainment value," his imaginative consideration for others, his love of children, animals, the sick, and all helpless things—all these were his. But perhaps his devotion to duty and his gaiety of heart combined were the two most outstanding characteristics of this man who so surely earned the title of "Beloved Physician." Our sincere sympathy goes out to his sorrowing wife and family.

W. R. M.

For the first 35 years of this century ROBERT MARSHALL practised in Shanghai, and his sudden death in London last month was a sad blow to a great number of old friends and patients from the Far East. Born in 1870 at Girvan, Ayrshire, he was educated at the Ayr Academy and at Glasgow University, graduating M.B., C.M. in 1891. For the next five years he was medical officer to the Rio Tinto Company at Huelva in Spain. While there he made observations on the malaria parasite, whose life history was being unfolded at the time. In 1896, in collaboration with Dr. George Thin, he read a paper on the subject to the Royal Medical and Chirurgical Society in London, taking his M.D. degree at Glasgow in the same year. For the next two years he worked in Bombay on the Plague Commission, and in 1899 transferred to Shanghai, where he joined Dr. Neil Macleod and Mr. W. Jennings Mills in a practice dating back to 1854. Shortly afterwards a fourth partner, Dr. E. L. Marsh, was taken in, and for thirty years his famous partnership was known throughout the Far East as the "M firm," though later additions and replacements did not keep strictly to the initial letter. In Shanghai Marshall found full scope for the development of his powers. The important professional posts he held he filled admirably. He was a good general surgeon, a wise administrator, a kindly and understanding family practitioner, and above all a man of action who never spared himself. In any emergency his action was as quick and decisive as his thought. Short in stature, deep chested, sandy haired, and of extraordinary vitality, he stood for the clean hard life. A fine athlete himself, he encouraged every kind of healthy recreation among his patients as the finest antidote to the depressing, and sometimes disastrous, effect that life in a strange land and trying climate is apt to produce. He was a living example of his own precepts, and retained a boyish vigour and enthusiasm almost up to the time of his death. He was a major in the Shanghai Volunteer Corps, President of the St. Andrew's Society, founder of one of the two chief golf clubs, and served in turn on the committees of most of the athletic clubs in the town. After retirement his sociable nature, and his considerable skill at billiards and bridge, made him an ever welcome member at the Hatched House Club in London. He leaves a widow, three married daughters, and one son, who is in practice at Brockenhurst and married to the daughter of the late Mr. Rowlands, of Guy's Hospital.—W. B. B.

Prof. JAMES DREVER, of Edinburgh University, speaking at the St. Andrews summer school of the Scottish Council for Health Education recently, drew attention to the part to be played by psychiatrists in the prevention and early treatment of certain organic diseases. He mentioned claims that certain psychological groups of people had gastric ulcers, other groups hypertension, and so on, and said that hospitals were admitting increasing numbers of sufferers from chronic disease of heart and stomach. It was to the detection of this type of disease that he expected psychiatrists would eventually make valuable contributions.

Universities and Colleges

UNIVERSITY OF LEEDS

The inaugural lecture of the faculty of medicine of the University of Leeds will be given in the Riley-Smith Hall of the University Union at 3.30 p.m. on Monday, Oct. 14, by Lieut.-Gen. Sir William MacArthur, K.C.B., D.S.O. Subject: Insect-borne disease and English history. Members of the medical profession are cordially invited to be present.

We are informed by the Society of Apothecaries of London that the name of O. G. Bennett was included in the list of successful candidates for the Diploma in Industrial Health (*Journal*, Sept. 7, p. 349) in error; it should have read "G. B. Oliver."

The Services

The Leishman, the Alexander, and the Parkes Memorial Prizes are open for award in the year 1947 for work done in 1946. Recommendations should be sent in through the usual Service channels with copies of original articles or reports of investigations to reach the hon. secretary, R.A.M.C. Prize Fund Committee, R.A.M. College, Millbank, London, S.W.1, by Dec. 31, 1946. The Leishman prize is for work done in any branch of medicine, surgery, or the allied sciences, or in connexion with the general duties of the R.A.M.C., or of the Army Dental Corps. The Alexander prize is for meritorious work in promoting the study and improvement of military medicine, military surgery, military hygiene, or military pathology. The Parkes prize is for outstanding merit in the promotion of the study of naval or military hygiene; it is open to regular serving medical officers on full pay in the Royal Navy, the Army, or the Indian Army. The Alexander and the Parkes prizes are not open to officers on the staffs of the Royal Naval Medical School, the Royal Army Medical College, or the Army School of Hygiene.

Medical News

A report of the Minister of Health's speech at the annual luncheon of the Society of Medical Officers of Health will be found in the *Supplement* this week.

The inaugural address of the first post-war course of clinical neurology at the National Hospital, Queen Square, Medical School will be given by Dr. Gordon Holmes, F.R.S., on Sept. 30, at 4 p.m.

At a clinical meeting of the Medical Society of the L.C.C. Service on Thursday, Oct. 3, at 3 p.m., at Dulwich Hospital, Dulwich Grove, S.E., the staffs of Dulwich and St. Olave's Hospitals will demonstrate cases. The hon. secretary of the Society is now Mr. Iain Matheson, F.R.C.S., at St. Giles's L.C.C. Hospital, S.E.5.

A meeting of the Faculty of Homoeopathy will be held at the London Homoeopathic Hospital on Thursday, Oct. 3, at 5 p.m., when the presidential address, "Looking Before and After," will be given by Dr. Charles Edwin Wheeler.

At a science meeting of the Colour Group of the Physical Society to be held at 3.0 p.m. on Oct. 3 at the Lighting Service Bureau, 2, Savoy Hill, W.C., papers will be read by Mr. N. E. G. Hill.

The Royal Sanitary Institute has arranged the following programme: Oct. 4 and 5 in the Town Hall, Lewes, papers on rural housing, and on army sanitation overseas. Oct. 9, 2.30 p.m., at 90, Buckingham Palace Road, S.W., discussion on the manufacture of ice-cream: the public health aspects, opened by Dr. W. R. Martine. Oct. 26, 10.30 a.m., in the Castle School, Cyfarthfa Park, Merthyr Tydfil, discussion on housing and its amenities.

The Minister of Health will distribute prizes at the Royal Dental Hospital of London School of Dental Surgery on Saturday, Oct. 5, at 3 p.m., at 32, Leicester Square.

The following public lectures will be delivered under the auspices of the Chadwick Trust: Tuesday, Oct. 8, at 2.30 p.m., at 26, Portland Place, W., Sir Arthur MacNally, "Sir Thomas More as Public Health Reformer"; Tuesday, Nov. 5, at 2.30 p.m., at London Missionary Society, 42, Broadway, S.W.1, Mr. A. Briggs, "Public Opinion and Public Health in the Age of Chadwick"; Thursday, Dec. 5, at 4.30 p.m., at St. Mary's Hospital Medical School, W., Prof. C. H. Stuart-Harris, "The Problem of Prevention of Acute Diseases of the Respiratory Tract, with particular reference to Influenza." Further particulars may be obtained from the secretary of the Trust (204, Abbey House, Westminster, S.W.1).

The programme for the 1946-7 session of the Chelsea Clinical Society has now been issued. The session will open with a dinner meeting at the South Kensington Hotel on Tuesday, Oct. 8, when the president, Dr. Ronald Jarman, will open a discussion on modern anaesthesia. The subjects for discussion at later meetings are as follows: Nov. 12, backache; Dec. 10, plastics in surgery and medicine; Jan. 14, osteopathy; Feb. 11, artificial insemination; March 11, industrial medicine.

The annual general meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday, Oct. 18. Private business will begin at 5 p.m., and will be followed by a dinner at the School at 7.30. Details are being posted to members. On Oct. 19 at 10.30 a.m. at the School, Dr. Donald Hunter and Dr. R. S. F. Schilling will address the Association on "Industrial Medicine in the U.S.A."

The date of the Louis Gross Memorial Lecture to be given under the auspices of the Montreal Clinical Society at the Jewish General Hospital, Montreal, has been changed from Oct. 16 to Oct. 23 (see *Journal*, Sept. 14, p. 404).

A new quarterly scientific journal named *Anaesthesia*, the organ of the Association of Anaesthetists of Great Britain and Ireland, is being published on Oct. 1. Intending subscribers should communicate with the publishers, George Pulman and Sons, Ltd., Thayer Street, London, W.1.

A clinical meeting of the Irish Tuberculosis Society will take place at Newcastle Sanatorium, Co. Wicklow, on Saturday, Oct. 19, at 2 p.m. Speakers will be: Dr. F. R. G. Heaf, "Recent Trends in Tuberculosis," followed by Dr. J. A. Deeny; Dr. Dorothy Price, "Is B.C.G. Vaccination a Practical Proposition in Ireland?" followed by Prof. J. C. Saunders; and Prof. F. J. Henry, "Surgery in the Treatment of Tuberculosis." A film (with explanatory commentary) dealing with the modern methods of the treatment of pulmonary tuberculosis in an Irish sanatorium will be included in the programme. Members wishing to attend should notify their intention of doing so to the honorary secretary, the Hospital, Newcastle, Co. Wicklow, not later than Oct. 5. Membership is open to all registered medical practitioners; annual subscription 10s. 6d.

The largest blood transfusion centre outside the London area was officially opened in Whitechapel, Liverpool, on Sept. 12, by Mr. C. W. Key, Parliamentary Secretary to the Ministry of Health. Operated by the National Blood Transfusion Service of the Ministry, it will serve a population of 3,500,000 people in Lancashire, Cheshire, and North Wales, supplying the needs of some seventy hospitals in that region.

Dr. A. L. Crockford has taken up the duties of secretary to St. Thomas's Hospital Medical School on the resignation of Dr. R. J. C. Thompson.

The Court of Governors of the London Hospital has appointed Mr. Osmond Clarke, F.R.C.S., to be surgeon and assistant director in the orthopaedic and accident department of the hospital.

EPIDEMIOLOGICAL NOTES

Discussion of Table

In *England and Wales* further falls in the incidence of measles 24, whooping-cough 152, and scarlet fever 76 were recorded, a rise was reported for diphtheria 22.

The fall in measles, which started at the end of June, continued, and small declines were recorded in most areas. The fall in whooping-cough was Lancashire 81, and only small variations were recorded in the remainder of the country. Small increases in the notifications of scarlet fever were general. The largest variations in the local returns of diphtheria were increases in Lancashire 15 and Durham 11.

Fourteen further cases of paratyphoid were reported from the outbreak in Yorkshire West Riding, Halifax C.B. The rise of 12 in the returns for dysentery was mainly due to an outbreak in Hertfordshire, Elstree R.D., which involved 16 persons.

In *Scotland* the notifications of diphtheria decreased by 15, while whooping-cough increased by 48. The cases of dysentery were only 3 less than in the preceding week, one-third of the total being recorded in Glasgow.

In *Eire* a further rise occurred in diarrhoea and enteritis; 51 of the 70 cases were reported from Dublin C.B. The notifications of measles increased by 12, while a decrease was recorded for scarlet fever 13 and whooping-cough 11.

In *Northern Ireland* the cases of diphtheria increased by 6; 10 of the 21 cases occurred in Belfast C.B.

Week Ending September 14

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 791, whooping-cough 1,744, diphtheria 255, measles 1,213, acute pneumonia 284, cerebrospinal fever 28, dysentery 68, acute poliomyelitis 22, paratyphoid 33, typhoid 17.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept. 7.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1946					1945 (Corresponding Week)

Vitamins in diseases of the muscular system

The following are suggestions for the application of vitamin therapy in certain diseases of the muscular system. Space limits the conditions that can be dealt with here but a sequel will appear in the next issue of the Journal.

Condition	Indications	Therapeutic Agents
VIC CONSTIPATION	Lack of tone affects the intestinal musculature. A mixture of the B vitamins, preferably in the form of food is found most effective.	BEMAX One heaped tablespoonful provides : 50/60 calories. 0.25, 0.5 mg. Vit. B ₁ , 1.0/1.5 mg. avail. Iron and appreciable amounts of the Vitamin B ₆ complex and Vitamin E.
STICITY; paralysis agitations.	Vitamin B ₆ has been found to reduce the muscular rigidity in ambulatory patients in whom the condition has not been of long standing.	PYRIDOXIN Vitamins Ltd. 10 mg. tablets, one or more thrice daily or 50-100 mg. daily by injection.
MYOPATHIES; muscular dystrophies and amyotrophic lateral sclerosis.	The disturbed muscle metabolism with increased creatinuria is found to respond in some cases to vitamin E together with other factors in whole wheat germ.	BEMAX At least 1 oz. daily together with FERTIL OIL (whole wheat germ oil stabilised and standardised), one 3 mg. capsule thrice daily.

Further particulars of the various products are obtainable on request from

Belling ELECTRIC BED WARMER

IT circulates warm air to every corner of the bed. Its smooth, rounded surface makes it quick and easy to slide in and out without catching and tearing bed linen. Cannot waste current as an Indicator Light shows when it is switched on. Can be used, too, for airing clothes, etc. Very strong, light and provided with handle for easy carrying. So economical too—25 hours warmth for 1 unit of electricity. Supplied complete with 12 ft. of 'flex' for connection to any lampholder or wall socket. **ABSOLUTELY SAFE.**

PRICE Purchase
33/- Tax
8/3 extra

Obtainable only through your usual electrical shop or showrooms.

3 water-soluble vitamins in ONE tablet

Stomatitis, anorexia, gastro-intestinal disturbances, states of debility, fatigue, and certain skin disorders are often associated with a lack of the water-soluble vitamins, nicotinic acid, B₁ and C. When these vitamins are supplied as an adjunct to treatment an improvement is usually noted. 'Nicorbin' tablets containing these nutrients, given thrice daily, supply the average adult requirement. During pregnancy and lactation, and during the process of wound healing the increased demands for these vitamins are met by supplying 'Nicorbin'. Whenever, from deficient intake or excessive physiological need, these water-soluble vitamins are required, 'Nicorbin' will prove valuable.

PRODUCT OF THE
GLAXO LABORATORIES

NICORBIN

COMPOSITION Each 'Nicorbin' Tablet contains:—Aneurine Hydrochloride (vitamin B₁) 1 mg. Ascorbic Acid (vitamin C) 25 mg. Nicotinic Acid (P.P. factor) 10 mg.

Para-Nasal Infections

treated with Albucid Soluble
Naso-Pharyngeal Solution

Albucid Soluble Naso-Pharyngeal Solution is a highly efficient method of applying local sulphonamide therapy to the naso-pharyngeal mucosa, providing rapid bacteriostatic control of the very prevalent infections of the naso-pharynx.

Its effective action is due to its remarkably low surface tension of only 37 dynes per cm. Moreover, Albucid Soluble is the only sulphonamide that can be presented in a neutral solution (pH 7.4).

IN BOTTLES OF ONE FLUID OUNCE × 10%

'Albucid' is the registered name which distinguishes sulphacetamide of British Schering manufacture.

THE CONTROL OF SCABIES

with

'TETMOSOL' SOAP

'Tetmosol' Soap is a pleasantly perfumed soap tablet containing 5% tetraethylthiuram monosulphide—a powerful sarcopticide. Used regularly in the manner of ordinary toilet soap, it has proved especially useful for controlling outbreaks of scabies in families, schools, hospitals, asylums, etc., having a curative effect as well as preventing infestation. There is no irritant effect on the skin and the method of use is simple and convenient so that the co-operation of scabies patients is readily secured.

'Tetmosol' Soap is issued in 3 oz. tablets, singly or in boxes of 36.

Literature supplied on request.

ANY QUESTIONS?

Electroencephalogram in Epilepsy

Q.—I have under my care a child aged 3. In the first year of life this child had frequent epileptic fits. Phenobarbitone $\frac{1}{2}$ gr. (32 mg.) night and morning was given and the fits completely ceased. The child has continued with the treatment for two years and is healthy and intelligent. Would electroencephalogram indicate whether there is still a liability to fits and whether the drug may now be left off?

A.—In a case of this sort a normal electroencephalogram would add weight to the view that the epileptic process has been terminated by phenobarbitone, but it would not indicate with certainty that no further fits will occur. It may well be—particularly in a child—that in spite of prolonged medication and the absence of fits the electroencephalogram will remain abnormal. In these circumstances an abnormality which is associated with paroxysmal disturbances in the records, known as larval outbursts, would indicate an active epileptic process, and would suggest the advisability of continuing treatment. Unfortunately difficulty is encountered in that the relationship of the number of larval outbursts to clinical attacks is very inconsistent. It seems that some subjects have a clinical attack whenever the epileptic process begins, whereas others have a high resistance to this process. It follows that the absence of any abnormality between clinical attacks does not necessarily reflect the prognosis for further attacks. This difficulty can to a large extent be overcome by obtaining serial records at intervals throughout treatment.

Recurrent Bee Stings

Q.—A farmer, aged 48, who has kept bees for 20 years and who has been stung many times, was stung again recently. The sensation was similar to that experienced under gas. He managed to stagger into the house and collapsed. He was blue in the face, his lips were swollen, he was very pale, and soon broke out into a profuse perspiration. He slowly "came to" as if he was coming out of an anaesthetic. What are the chances of the same reaction should he be stung again?

A.—The attack was an allergic or anaphylactic reaction and the chances of a similar attack if stung again are high. He should get rid of his bees and, so far as possible, avoid further bee stings. Hyposensitization with bee antigen can be carried out and might be considered. The reaction due to any future bee sting would then be at least modified. In view of the severity of the reaction extra care would be necessary with regard to the dosage. Adrenaline is the best and quickest antidote.

Anaesthesia for Perineal Tear

Q.—Can you give me any information about the technique of local anaesthesia for repair of perineal tear?

A.—Various methods of local anaesthesia, or as it is more correctly termed of local analgesia, for the repair of the torn perineum or of an episiotomy have been described. A simple and entirely satisfactory method consists in local infiltration of the wound in the perineum and posterior vaginal wall. A

sterile solution of procaine, 1 or 2% strength, with 1:100,000 adrenaline is used, or alternatively one of the proprietary self-sterilizing solutions, which are convenient in domiciliary practice. It is advisable to use a syringe of 10 or 20 ml. capacity and two needles, one hypodermic and one intramuscular (gauges 17 and 12).

The patient is placed in the lithotomy position and the vulva is cleansed with an antiseptic solution. With the fine needle a weal is raised at the posterior end of the wound. With the larger needle the tissues under the edge of the skin and of the vaginal mucosa are thoroughly infiltrated to a width of about half an inch. Finally the deeper tissues are infiltrated. A swab soaked in the analgesic solution may be placed on the raw surface. It is necessary to wait at least five minutes before attempting to insert any sutures. This period of waiting, though perhaps tedious to the operator, is well worth while, as by this means a much more satisfactory analgesia is obtained.

Pitressin Test in Epilepsy

Q.—How is the pitressin test in epilepsy carried out? What is its value and are there any dangers attached to the procedure?

A.—The water-pitressin test is carried out as follows: The patient is given copious fluid, his fluid intake and output being measured, and he is weighed night and morning. An increase of 2% in the body weight with an excess of fluid intake over output is taken as proof that a positive water balance has been established. This point is usually reached in forty-eight hours. Pitressin 0.25 ml. is then given intramuscularly with 300 ml. of water by the mouth. Further doses of pitressin, 0.5 ml., with 300 ml. of water, are given every two hours to a total of ten injections, unless a fit occurs before, when the test is stopped. A positive result may be expected in at least 30% of epileptic subjects. The test is contraindicated in diabetes mellitus, nephritis, arteriosclerosis, and myocardial degeneration. Otherwise the test appears to be free from danger.

D.D.T. and Animals' Parasites

Q.—Is D.D.T. of any use against sheep ticks and, if so, can it be applied to a dog's coat without noxious effects to the dog?

A.—D.D.T. has been found effective as a constituent of a sheep dip against the tick *Ixodes ricinus* L. The easiest way to apply it to a dog's coat would be by shaking in a powder containing 10% D.D.T. Such a treatment would not affect the dog.

Chronic Osteomyelitis

Q.—What is the treatment of chronic osteomyelitis? Is it justifiable to treat cases with discharging sinuses in the outpatient department?

A.—Both depend upon so much else: first, the age of the patient, cause of the infection, and number of lesions present. Generally speaking if one is dealing with an old-standing haematogenous staphylococcal infection the local lesion can often be dealt with by relatively radical surgical measures. Certainly sequestra should be removed and cavities opened up for adequate drainage and to facilitate healing. Direct chemotherapeutic attack may hasten the cleaning up of such cavities, but general systemic penicillin in very chronic cases has not yet shown the dramatic effects produced in acute haematogenous osteomyelitis. The opening up of chronic bone cavities must be tempered with some moderation in view of the risks of later pathological fracture. When such cavities are relatively clean further surgical treatment should more frequently be considered in order to obliterate them and give sound final closure. The trouble with the treatment of bone cavities is the natural rigidity of the walls, which, of course, prevents their collapse when the active infection has died down. Organisms tend to remain latent within the extensive scar tissue. In chronic osteomyelitis or, as Rutherford Morrison stressed that it should be called, *osteitis* due to compound fractures or war wounds, Robertson and Barron have shown how excision of scar tissue and infected bone, followed by the insertion of muscle flaps or skin grafting, and later by the obliteration of cavities with iliac cancellous bone grafting, can heal chronic offensive disability.

The answer to the second part of the question is that it depends on the "out-patient department." Treatment as suggested above? Certainly not. The week-in, week-out dressing of chronic sinuses? Certainly not, for this is not treatment of the disease. Treatment as part of a planned programme may have some place in an out-patient department if the department is such that complete surgical precautions are followed: Too often cases of chronic osteitis are regarded as dirty problems which cannot be made dirtier—let alone the impunity with which such cases are treated alongside cases of industrial injuries to the hand, burns, and other wounds.

Treatment of Empyema

Q.—What is the accepted treatment for acute and chronic empyema? When is rib-resection performed?

A.—A full answer to this question would require a volume. Treatment of acute empyema varies greatly according to the causative organism, the presence of accompanying lesions in the lung and elsewhere, and anatomical aspects. The exact place of penicillin in the treatment of acute empyema has still to be determined. With all these variable factors there is no one "accepted treatment" for empyema, and it is impossible in a short answer to deal in any useful way with the first part of this question.

With regard to the second part—in acute empyema rib-resection is indicated only when the collection of pus is localized by pleural adhesions, which will generally be the case if the pus has become thick. While the pus is thin and there is no evidence of adequate pleural adhesions ("pyothorax" rather than localized "empyema"), the pus must be removed by aspiration or by intercostal drainage. Drainage by a closed method may be indicated even after rib-resection. The most important part of the treatment is to secure complete re-expansion of the lung. This is helped by the early application of suitable active inspiratory breathing exercises. The tube should not be removed from a drained empyema so long as there is evidence that any residual empyema space remains; and if there is any doubt about this it is well to outline the sinus and residual space, if any, with iodized oil and take radiographs before deciding about removal of the tube. Recently some success has been reported in the treatment of acute empyema caused by penicillin-sensitive organisms by aspiration and injection of penicillin until the pus becomes thick, followed by intercostal drainage, which is used as a method of continuing the intermittent aspirations and injections of penicillin. The exact place of this line of treatment has still to be determined. With regard to chronic empyema it should be realized, first, that many such empyemata are the result of inadequate treatment of acute empyema. In any case of chronic empyema the diagnosis is not complete until the underlying disease, especially tuberculosis, new-growth, and chronic suppurative processes in the lung, has been considered. The diagnosis of chronic simple empyema having been thus established the first step is to secure free drainage by adequate rib-resection. Suction drainage, breathing exercises, and, unless there is a pleuro-bronchial fistula, irrigation of the cavity should then be instituted. If this does not result in obliteration of the empyema space plastic operations on the chest wall, combined in resistant cases with one of the several special surgical techniques for mobilization of the thickened parietal pleura, will become necessary.

Sequelae of Encephalitis Lethargica

Q.—Is there any effective treatment for chronic encephalitis lethargica? Have penicillin, the sulphonamides, fever therapy, protein shock, or repeated lumbar punctures any proved value in the treatment of this condition?

A.—Penicillin and the sulphonamides are of no value in the treatment of chronic encephalitis lethargica. There is no reason to suppose that repeated lumbar puncture would be helpful. Artificial pyrexia, most simply induced by the intravenous injection of T.A.B. or *B. coli* vaccine, has a limited value, especially for encephalitic parkinsonism, when the disorder is not too far advanced.

LETTERS, NOTES, ETC.

Medical Service in Australia

SIR ERNEST GRAHAM-LITTLE, M.P., writes: Dr. Gilliland quoted a letter from the High Commissioner of Australia received by *Medical World*, the organ of the Medical Practitioners' Union, containing the statement: "No Bill to establish a State medical service has been introduced into the Commonwealth Parliament of Australia (*B.M.J.*, Sept. 14, p. 407). Dr. Gilliland declares that this "condition" "calls for explanation from me," and I hope you will all me to supply it. The information from my correspondent in Canberra upon which I based my letter (*B.M.J.*, Aug. 24) was to the effect that an Act containing proposals for State-provided and partly State-controlled medical services was passed some years ago by the Socialist Government in Australia; that the medical profession in Australia, regarding these proposals as a threat to their freedom, refused to accept service under the Act and that consequently it has not been put into operation up to the present date. (I would like to see the letter from the M.P.U. (a consistent advocate of State service) that elicited the above very guarded reply which it is to be noted, does not "contradict" my statements but merely repudiates a description (which nobody offered) of that Act as "establishing a State medical service." (Fortunately, as the Minister of Health, confronted with the Australian revolt, realized, one cannot establish a State medical service without the consent of the doctors. I have not seen the text of the Australian Act and I am writing to Canberra asking to be furnished with a copy, but from my correspondent's description it would seem to present a general resemblance to Mr. Bevan's Bill. A State service postulates national full-time salaried pensionable medical personnel which has been the declared goal of the Socialists for more than a decade. (See *Hansa* May 1, Col. 225.) Mr. Bevan's Bill goes a very long way towards achieving this aim: he prudently forbears for the moment to do all the way, but he has not forgone the hope and expectation that this aim will be achieved when, as he expressed it in the debate, the time is "ripe" for that ultimate complete fulfilment. It is significant that a motion to introduce such a service in Britain was proposed to the Representative Body in 1943 and was rejected by twenty-to-one majority at a meeting attended by practically the entire membership of that body: their verdict has been repeated on several occasions since that date. It is clear that our Australian colleagues saw in the Act which they rejected a similar threat to their freedom, and I submit their example is one which we must well follow now.

Varicose Ulcers and Penicillin

DR. W. T. E. BLACKMORE (Abergavenny) writes: A reference to Letters, Notes, etc., in the *Journal* of Aug. 17 (p. 252) prompts me to relate my experience of the value of penicillin cream in the treatment of varicose ulcers. Thirty-two varicose ulcers, with penicillin-sensitive organisms, have been successfully treated during the last ten months by adopting the following technique. After thorough cleansing with warm saline a dressing of penicillin cream (100,000 units to 1 oz. (30 g.)) is applied on a gauze pad. The entire lower leg—foot to knee—is then firmly bandaged with a supporting bandage of the Unna type and a second layer of gauze bandage applied over it. This is left in position for a week the patient being advised to pursue in the meantime his or her normal activities; then the dressing is renewed. The average length of treatment is seven to eight weeks, that is, seven or eight dressings after which the ulcer is firmly healed; and treatment of the underlying cause is then carried out. One case, which took twelve weeks to clear, was a varicose ulcer some 6 by 2½ in. (15 by 6.4 cm.); so one is entitled to assume that this form of treatment is of definite value.

An Offer of Medical Equipment

A medical man in the South of England informs us that the doctor son of one of his patients was killed in Burma. The father has a sphygmomanometer, an electric ophthalmoscope, and an auroscope; also one or two oddments. He would like to give the lot to a doctor who has lost his equipment by reason of war, or to a doctor returning from the Forces and in need of professional apparatus. Letters addressed to this office will be forwarded.

Corrections

We apologize for the oversight by which the words "encephalitis" and "encephalopathy" were misprinted in the footnote to C. E. S. Harris's letter last week (p. 442).

The word "undermined" should have read "underlined." Dr. Anthony C. Hamer's letter published under "Tobacco and Ulcer Dyspepsia" in the *Journal* of Sept. 14, p. 402.

A misprint occurred in FL-Lieut. W. P. U. Jackson's letter (Sept. 14, p. 403). The word "trend" in the first sentence should of course be "triad," and the clause should run "the triad of symptoms polyarthritides, urethritis, and conjunctivitis noted in my article (Aug. 10, p. 197) as being characteristic of Reiter's disease may also be associated with bacillary dysentery."

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 28 1946

British Medical Association REPORT OF INSURANCE ACTS COMMITTEE, 1946

Chairman

Dr. E. A. Gregg was reappointed Chairman of the Committee for the session 1945-6.

Obituary

The Committee regrets to record the deaths of:

Sir Kaye Le Fleming (Wimborne, Dorset), member of the Insurance Acts Committee, 1922-39; Chairman of the Conference of L.M. and P. Committees, 1924-9; past Chairman of the Representative Body and Chairman of Council of the B.M.A. Dr. David Rorie (Aberdeen), member of the Insurance Acts Committee, 1923-5; member of the Insurance Acts Scottish Subcommittee, 1923-5. Dr. W. H. Smailes (Huddersfield), member of the Insurance Acts Committee, 1927-46; member of Council of the B.M.A., 1938-9. Dr. W. E. Thomas (Ystrad Rhondda, Glam.), member of the Insurance Acts Committee, 1922-44; member of the Council of the B.M.A., 1923-44.

Ministry's Distribution Committee

The Committee's nominees on the Ministry of Health Distribution Committee in connexion with the 'Central Practitioners' and Mileage Funds are: Dr. E. A. Gregg (London), Dr. D. J. B. Wilson (High Wycombe, Bucks), Dr. D. B. Evans (Coedpoeth), and the Assistant Secretary (Dr. L. S. Potter), together with Dr. J. A. Pridham (Weymouth), Dr. J. C. Pearce (Diss, Norfolk), and Dr. J. D. Wells (Billericay), when questions concerning mileage are under consideration.

INSURANCE CAPITATION FEE

The report of the Spens Committee (*Supplement*, May 18, 1946) was issued at the beginning of May. Its findings confirm the statement, made repeatedly by the Insurance Acts Committee, that the remuneration for the treatment of insured persons is and has been quite inadequate. The Committee welcomed and approved the Majority Report of the Spens Committee, and a communication to this effect was sent to the Minister of Health. The Council and the Representative Body of the B.M.A. have since adopted similar resolutions.

In March the Committee, without waiting for the Spens Committee's report, decided to make an application for an increase in the insurance capitation fee, with effect from Jan. 1, 1946, and to ask the Minister of Health to receive a deputation to discuss the matter. This step was taken, not only because of the deep and widespread dissatisfaction among insurance practitioners with the existing fee but because the present Minister's two predecessors had given an undertaking that the whole question would be re-examined "from the ground up" as soon as the war was over. The Minister's reply was that he felt that such a discussion should be postponed until the Spens Committee's report had been published and he had had an opportunity of studying it.

Eventually the Minister received a deputation, but no progress was made because the Minister persisted in the view that the first step should be to translate the Spens recommendations into terms of remuneration for services under the proposed new Health Service. At this stage the Minister had not indicated his acceptance of the substance of these recommendations. Sub-

sequently interviews with Ministry officials took place. The Committee's representatives made it clear that they were not authorized to enter into discussions on the remuneration of general practitioners under the new Health Service. It was demonstrated to the Ministry that it was possible to determine, in the light of the Spens recommendations, what the appropriate capitation fee for present services should be, without embarking on discussions to be covered by Regulations under legislation not yet approved by Parliament.

Subsequently the Committee's representatives were informed that, as they were unwilling to enter into discussions on remuneration under the new Health Service, it would not be possible for the Minister to do more than make an arrangement for the interim period while negotiations were proceeding on the long-term agreement. The Minister put forward a capitation fee of 12s. 6d., with effect from Jan. 1, 1946. This was considered at a special meeting of the Committee on July 22, when the following resolutions were adopted and forwarded to the Ministry:

That the Minister of Health be informed that the Insurance Acts Committee, while it welcomes the Minister's acceptance of the Majority Report of the Spens Committee and his recognition of the inadequacy of the insurance capitation fee, regards the proposed increase of two shillings in the capitation fee as gravely inadequate.

That the Minister be informed that the Insurance Acts Committee would be prepared to recommend insurance practitioners to accept, in the interim, a capitation fee of fifteen shillings, retrospective to Jan. 1, 1946. The Committee would be willing, if the Minister so prefers, that the Spens Committee should be asked to state the implications of its Majority Report in relation to the current insurance capitation fee, upon the understanding that the Insurance Acts Committee and the Minister accept, in advance, the findings of that Committee.

Further correspondence took place with the Ministry, in the course of which it was pointed out to the Ministry that a definite promise had been given in 1941, and repeated in subsequent years, that the capitation fee for services rendered at the present time would be considered "from the ground up" and quite apart from the new Service. It was with this promise in mind that the Ministry proposed the appointment of the Spens Committee, which would, to use the Ministry's words (in 1944), "approach the whole subject of public remuneration of the general practitioner with an open mind and a clear field," and whose findings "would apply irrespective of the institution of any National Health Service and would directly bear upon existing conditions under the present National Health Insurance scheme . . . to give effect, indeed, to the assurance given by Mr. Ernest Brown last year that the whole question of public remuneration of the general practitioner should be approached anew 'from the ground up.'"

The Minister persists in his view that it is impossible at the present time to consider the remuneration of general practitioners in the proposed new Health Service and the present N.H.I. Service separately. As his offers to discuss the two matters concurrently cannot be accepted by the Insurance Acts Committee he has given instructions for the 2s. increase, mentioned above, to be paid to insurance practitioners, with effect from Jan. 1, 1946. In other words, he imposes the condition

that negotiations for remuneration for a Service not yet approved by law must precede consideration of proper remuneration for a Service already in being, and in the absence of acceptance of such a condition he arbitrarily awards an increase which is regarded as completely inadequate and does not fully implement the report of the Body set up to advise on the subject—namely, the Spens Committee.

The Insurance Acts Committee at its meeting on September 5 had before it a full report on the situation. It could come to no other conclusion than that the Minister of Health was failing to redeem the promises already given that the adequacy of the capitation fee would be the subject of a complete investigation after the war, and that such an investigation would be conducted in the light of the report of the Spens Committee. No such investigation has in fact taken place, and as the Insurance Acts Committee is unanimous in its view that the offer of a 2s. increase is totally inadequate it has decided that it cannot recommend insurance practitioners to continue to give service for an inadequate capitation fee. The Committee is willing that the matter should be referred to the Spens Committee itself, or some other agreed body, and if this is done it is prepared to accept, on behalf of the insurance practitioners, the findings of such a body.

A recommendation on these lines to the forthcoming Annual Conference is set out below. This recommendation has been sent to Panel Committees with a request to call meetings of all insurance practitioners in their areas to discuss it and instruct representatives to the Conference. It should be emphasized that the instrument of resignation is proposed, not to obtain a particular sum but to press for the proper application of the Spens Committee's report to the current capitation fee.

The Insurance Acts Committee is confident that the lead it is now giving to insurance practitioners will be solidly supported. The principle at stake is similar in character to the principle for which 95% of insurance practitioners signed resignation forms in the autumn of 1923. On that occasion their action was successful. The same determination must be shown on the present occasion.

Recommendation: That, in view of the Minister's failure properly to apply the report of the Spens Committee to the current capitation fee—despite explicit Government promises that this would be done—and in view of the grave inadequacy of 12s. 6d. as remuneration for assuming medical responsibility for an insured person for a year, it be recommended to all insurance practitioners in England and Wales, Scotland and Northern Ireland to place their resignations from the National Health Insurance Service in the hands of the Insurance Acts Committee and to authorize that Committee at its discretion to put in such resignations to Insurance Committees unless the Minister is willing fully to apply the Spens Report to the current capitation fee with effect at least from Jan. 1, 1946, or, failing agreement, to refer to the Spens Committee or a representative section of that Committee, or other agreed independent body, the interpretation of the Spens Committee Report in relation to the current capitation fee, both parties agreeing in advance to accept the findings of such body.

NATIONAL HEALTH SERVICE

The resolutions of the Special Conference of Representatives Local Medical and Panel Committees on April 30 were passed on to the Special Representative Meeting on the following day. It will be remembered that the Special Conference expressed general approval of the Council's Report to the Special Representative Meeting.

Several points have been raised by Panel Committees on matters relating to the terms of service of practitioners participating in the proposed National Health Service, and these will be brought to the notice of the Negotiating Committee at the appropriate time.

JOINT COMMITTEE WITH PHARMACISTS

The Council of the B.M.A. agreed to a suggestion from the Pharmaceutical Society of Great Britain for the appointment of a joint *ad hoc* committee of doctors and pharmacists to consider matters of common interest arising out of the proposals for a National Health Service. The Association's representatives are the Chairman of Council, three appointed by the General Practice Committee, three appointed by the Insurance Acts Committee, and one appointed by the Scottish

Committee. The pharmacists represent the Pharmaceutical Society, the National Pharmaceutical Union and the Pharmaceutical Standing Committee (Scotland). One meeting of the Joint Committee has been held, and among the subjects discussed was the question of dispensing in rural districts. No recommendations have yet been submitted to the constituent bodies of the Joint Committee.

SCHEME FOR AN EMERGENCY GENERAL PRACTITIONER MEDICAL SERVICE

In conjunction with the General Practice Committee, the Insurance Acts Committee has been endeavouring to evolve a scheme for a medical service which could be put into operation in the event of the profession being unwilling to accept the Government's proposals for a National Health Service. Such a scheme would take the place of the present N.H.I. medical service, other persons being treated privately except where local contract arrangements of one kind or another are in operation.

The draft scheme was sent to Panel Committees for their observations. A number of Committees do not believe such a scheme to be practicable, especially in rural areas. To sum up, there appears to be a strong body of opinion that if the profession decides not to accept service under the proposed National Health Service there should be a return to private practice so far as the present insured population is concerned. The Committee has, therefore, abandoned as impracticable any idea of a scheme for the whole country, but is revising its draft scheme to meet, as far as possible, the wishes of those areas, including some of the largest in the country, which would like to be prepared with an alternative general practitioner medical service on a contract basis.

TERMINATION OF PROVISIONS FOR PROTECTION OF PRACTICES

The Ministry of Health recently decided to issue instruction to Insurance Committees on the termination of the special wartime provisions for the protection of the insurance practices of absentee practitioners. These wartime provisions were intended to remain in operation until a date to be agreed between the Panel and Insurance Committees or, failing agreement, no later than the date of the termination of the emergency, as fixed by Order in Council. It was announced, however, that no such Order in Council would be issued, and the date beyond which the wartime provisions will not continue to operate has been left for agreement between the Insurance and Panel Committees in each area.

PROTECTION OF PRACTICES—ADJUSTMENT OF LISTS

At the request of the 1945 Annual Conference consideration was given to the practicability of making provision, on a national basis, for returning insurance practitioners to receive for a limited period payment out of the Local Practitioner Fund of not less than they were receiving in 1939. The intention was that the practitioner should have the benefit of the payment for six quarters following his return to his practice unless he had succeeded in building up his practice to the 1939 level earlier, when the arrangement would cease to apply to him. A national scheme of this nature, involving the creation of a central pool, would be administratively possible only if a very high percentage of Panel Committees throughout the country were willing to co-operate and could give the necessary assurance that their constituents were in favour of the scheme. An inquiry revealed that in a substantial proportion of areas the Panel Committees were not in favour of dealing with the problem on a national basis, preferring that it should be left to each area to make its own arrangements if it considered that any action at all was desirable.

In the circumstances, the Insurance Acts Committee decided that it could not press the Ministry of Health to put the necessary machinery into operation for the creation of a national pool for this purpose. The Committee advised any area that wished to guarantee, for a limited period, the pre-war insurance income of a returning practitioner, to seek the collaboration of the Insurance Committee in securing the necessary amendments of the local Allocation and Distribution Schemes.

It is understood that, provided it can be shown that there is no substantial opposition from insurance practitioners in the area, the Ministry of Health would be willing to sanction amendments of the schemes.

POST-WAR FINANCIAL ASSISTANCE

The 1945 Annual Conference asked that the new scheme to enable medical practitioners to obtain financial assistance on advantageous terms be sent to all serving doctors. The scheme is referred to in the booklet *The Returning Doctor* which was published by the B.M.A. and issued to every doctor on demobilization. The Committee felt that in view of the paper shortage and other difficulties associated with the preparation and issue of a separate booklet, the reference to the scheme in *The Returning Doctor* would meet the position of serving doctors.

MEDICAL RECORDS OF DEMOBILIZED SERVICES PERSONNEL

The 1945 Annual Conference (Min. 26) asked that it should be made possible for Clerks to Insurance Committees to obtain a précis of the medical record of a demobilized person on the request of the patient's doctor and subject to the patient's permission. Arrangements to meet this request have now been made.

Service medical histories of demobilized persons are held by the appropriate Service Department and applications should not be made to the Ministry of Pensions. The War Office and Admiralty are prepared to furnish a photostatic copy and the Air Ministry a summary of the Service medical history to the doctor responsible for the patient's treatment, provided that the doctor gives an assurance that it is required for actual medical treatment and that no disclosure will be made from the documents. Applications, which should quote the Service particulars and be accompanied by the patient's written consent, should be addressed by the doctor as follows: *Royal Navy*, The Medical Director of the Navy, Queen's House, 64, St. James Street, S.W.1. *Army*, The Secretary, War Office (C2a), Whitehall, S.W.1. *Royal Air Force*, The Under-Secretary of State, Air Ministry (MA2), London, W.C.2.

TITLE TO MEDICAL BENEFIT OF DISCHARGED SERVICES PERSONNEL

The Annual Conference (Min. 71) expressed the view that discharged Services personnel should not be supplied with medical cards until they actually re-enter insurable employment. Men and women discharged from the Forces are entitled to medical benefit immediately they are demobilized and the Committee is assured that in computing the numbers of persons entitled to medical benefit the Government Actuary takes into consideration details of discharges and releases furnished to him by the Service Departments and the Ministry of National Insurance, and appropriate payments are made into the Central Practitioners' Fund.

Generally speaking every man and woman below commissioned rank who leaves the Forces is immediately entitled to a "free period" of insurance, including medical benefit. So far as commissioned officers are concerned the position is somewhat different. An officer is entitled to medical benefit after demobilization if he was compulsorily insured under the N.H.I. Act during his service. Liability to compulsory insurance during service is determined in the following way. Regular officers, that is officers appointed to permanent commissions and, in the case of the Navy, to permanent warrants, are not compulsorily insurable. Other officers, that is officers of the reserve and auxiliary forces and officers appointed to temporary commissions or warrants, are compulsorily insurable during their period of service if they were to any extent insured under the National Health Insurance and/or the Contributory Pensions Acts at the date of calling up or at the commencement of commissioned service. The only exception to the latter is that officers appointed from the ranks (and therefore insured at the commencement of their commissioned service) have the option of electing within two months from the date of their appointment to discontinue their insurance if they were not insured when their war service began.

IRREGULAR REMOVAL OF NAMES FROM DOCTORS' LISTS

The 1945 Conference resolutions (Mins. 38 and 39) on the subject of the irregular removal of names from doctors' lists have been carefully considered by the Committee. The increase in this irregularity is understood to be largely due to the abnormal movements of insured persons during the final stages of the war and the beginning of the post-war period, and to the shortage and inexperience of clerical staffs. The Committee decided that if, after a reasonable interval, there is no improvement in the position, it will again press the Ministry for vigorous action.

NEW ENTRANTS INTO INSURANCE

Minutes 35 and 36 of the 1945 Annual Conference, recommending that Form Med. 50 be amended to show that the insured person is already employed, and asking that some way be found for issuing medical cards to new entrants immediately they become insured, have been considered by the Committee. It has not been possible to persuade the Ministry to accept the Committee's suggestions either for a form of certificate on Form Med. 50 for completion by the employer or a space on the form for the insertion of the name and address of the employer. The Ministry has, however, amended the insured person's contribution card by the inclusion of the following paragraph:

"You are entitled to Medical Benefit as soon as you enter insurable employment. If you need medical treatment and have no medical card, get a Form Med. 50 at a Post Office, fill it in and give it to an insurance doctor before posting it to the Insurance Committee—address obtainable at the Post Office. Failing that, tell the doctor (who can require a deposit) that you are an insured person."

The Committee is not satisfied that this new paragraph will be effective in speeding up the issue of medical cards to new entrants into insurance. The new paragraph is also unsatisfactory in that the direction to obtain a medical card is limited to those who are in need of treatment. If evidence is forthcoming that the delay in the issue of medical cards continues to give rise to difficulties, the Committee will again take the matter up with the Ministry.

ELECTION OF PANEL COMMITTEES

In reply to the request of the Annual Conference (Min. 59) for a resumption of the election of Panel Committees, the Ministry stated that it did not consider it would be justified in issuing a general direction on the subject to Panel Committees. At the same time the Ministry is prepared to consider any application made by a Panel Committee to fix the date for the termination of the term of office of its members.

REGIONAL MEDICAL SERVICE

Reference of Patients to Specialists

In the Committee's last Report to the Conference (paras. 25-28) an account was given of exchanges with the Ministry of Health on the attitude of the Ministry in cases where an insured person is referred to a Divisional Medical Officer for an independent medical examination, and a tuberculous condition is diagnosed. The Ministry of Health gave an assurance that in those cases where the opinion of a specialist was considered to be desirable for reasons other than to enable the examining medical officer to report whether or not the insured person was incapable of work, no steps would be taken for the specialist examination without consulting the insured person's own doctor. This was satisfactory up to a point, but it was thought that it would be in the interest of the patient, the N.H.I. medical service, and the maintenance of a high standard in the settlement of cases of doubtful incapacity for work if, in the first instance, the patient's own doctor was given an opportunity of arranging for a second opinion. The Ministry does not consider it practicable or desirable to adopt this suggestion, expressing the opinion that by keeping the patient's own doctor informed of arrangements for a specialist examination the interests of patient and doctor are adequately met.

The Ministry is being pressed to reconsider its decision, particularly on the ground that it is not sufficient that the

insurance doctor is invited to be present at the examination by the specialist. The present arrangement does not give the patient or his doctor any choice of the specialist chosen for the examination.

Examination of Pregnant Women

The Ministry has again been pressed to agree that an examination of a pregnant woman by a Regional Medical Officer should be made at home if she is within eight weeks of the expected date of confinement. In 1935 it was arranged that any woman referred for examination, who was stated by her doctor to have reached the 36th week of pregnancy, would not be summoned to an examination centre. The Ministry is prepared to extend this arrangement to women who are stated to have reached the 34th week of pregnancy, but the Insurance Acts Committee is urging that the 32nd week should be the outside limit.

It is necessary, in order that full advantage may be taken of the arrangement described above, for a practitioner to state on Form R.M.2 the stage of pregnancy in weeks that has been reached.

Sickness Benefit in Relation to Pregnancy

At the Committee's request the Ministry of Health approached the Ministry of National Insurance with a view to arranging that in cases where Sickness Benefit is paid for incapacity for work due to pregnancy the attending doctor would not be required to give more than one certificate to cover the whole period. The Ministry of National Insurance indicated that it could not recommend Approved Societies to accept a single certificate to cover the whole period in cases where the cause of incapacity is due solely to pregnancy. The Insurance Acts Committee has made the further suggestion that in cases where the doctor is satisfied that the patient will not be capable of work until after her confinement it should be possible for the doctor to make use of the Special Intermediate Certificate forthwith.

Min. 43 of the 1945 Annual Conference expressed the view that employed women should be given a weekly maternity benefit for a total period of thirteen weeks, extending on both sides of the date of confinement. Such a benefit, amounting to 36s. a week, will be paid when the new National Insurance Act becomes operative.

POSTGRADUATE COURSES FOR INSURANCE DOCTORS

The Ministry of Health is contemplating the reintroduction of postgraduate courses for insurance practitioners, pending the provision of such facilities under the National Health Service. The proposal is dependent upon the universities being willing to continue, during 1947, the courses of postgraduate instruction for demobilized doctors, the demand for which it is anticipated will shortly decline.

The proposed course may be of several types: (a) a two weeks' intensive course of 22 sessions in general medicine; (b) a two weeks' intensive course of 22 sessions in some specialized subject approved by the Ministry; (c) a one week's intensive course of 11 sessions in general medicine; (d) a one week's intensive course of 11 sessions in some approved specialized subject; (e) an extended course—e.g., two afternoons a week for 11 weeks in general medicine or some approved special subject.

As in the case of similar courses before the war, the syllabus will be subject to the general approval of the Minister of Health. An insurance practitioner will be given freedom of choice of the centres where courses are available. In the case of a specialized subject the Ministry will exercise its veto only in cases where the subject is considered to be inappropriate.

An insurance practitioner will be allowed to take one two-week course during 1947, or two one-week courses. To be eligible for financial assistance he must (a) have at least 300 insured persons on his list or lists, if practising in an urban area, or 150 if practising in a rural area; (b) have been registrably qualified for at least three years; and (c) must not have attended one of the courses for demobilized officers.

Financial assistance towards the expenses of insurance practitioners attending the courses will be paid out of National

Health Insurance funds. Such expenses will include a gratuity for the provision of a locum tenens, where necessary; the fee for the course; subsistence allowance while attending the course, and actual travelling expenses.

In due course the Ministry proposes to send a circular on the subject to every Insurance Committee, with copies to Panel Committees, for their information. There will also be appropriate announcements in the medical press.

CERTIFICATION

The Ministry of Health is again being asked to take appropriate action to prevent official National Health Insurance certificate forms from being used for other than N.H.I. purposes.

Revision of National Health Insurance Certificate Forms

The 1945 Annual Conference (Min. 29) asked that consideration be given to the need for a revision of the certificate forms, both in the number of different forms and the wording of them at present in use. The suggestion has been noted for consideration at a favourable opportunity and will be brought to the notice of any committee which will be dealing with the terms and conditions of employment under National Health Insurance.

DISPENSING AND PRESCRIBING

Dispensing Capitation Fee

As the result of representations to the Ministry of Health the dispensing capitation fee has been increased from 3s. to 3s. 6d. per annum, with effect from November 1, 1946. Consideration is being given by the Committee to the adequacy of this increase in view of the heavy rise in the cost of drugs, etc. There is also dissatisfaction with the date from which the increase is effective. In the autumn of 1945 insurance chemists were awarded an increase in their dispensing fees which was dated back to Jan. 1, 1945.

Penicillin

The Ministry of Health has included "penicillin and preparations of penicillin" in the list of drugs appended to Part II of the Distribution Scheme, with effect from June 1, 1946. In the interest of the economical use of penicillin it has been suggested to the Ministry that direct pathological facilities should be made available to insurance practitioners for the testing of organisms of certain infections in relation to their sensitivity to penicillin. It has also been represented to the Ministry that doctors should be given priority for the supply of refrigerators for the economical preservation of penicillin and other drugs.

Drug Tariff

The Ministry of Health has been asked to revert to the pre-war practice of issuing the Drug Tariff to individual insurance practitioners.

Schedule of Appliances

An application has been made to the Ministry of Health for the addition to the Schedule of Appliances of a preparation of sterile vaseline gauze for use in the treatment of burns and wounds.

GROUPING OF AREAS FOR ELECTION OF I.A.C.

The Committee was asked by the Conference to reconsider the grouping of areas for the election of direct representatives on the Insurance Acts Committee, with special reference to the position of Derbyshire. The committee has to report that it has found it impossible to rearrange the groups without serious disturbance to the basic foundation of the present arrangement of areas.

FEES FOR PART-TIME R.M.O.s

The Ministry of Health has increased from two to two and a half guineas, with effect from March 1, 1946, the sessional fee payable to medical practitioners employed as part-time Regional Medical Officers in the examination of cases of doubtful incapacity for work. The announcement of this increase followed a request by the Insurance Acts Committee for an increase in the fee to three guineas.

DEMOBILIZATION OF PRACTITIONERS FROM H.M. FORCES

At the request of the Conference the Central Medical War Committee was asked to agree to increase its membership so as to provide for the representation of medical practitioners who have held commissions in territorial or temporarily mobilized forces since September, 1939. Three such representatives were appointed, and they have been added to the Services Committee of the C.M.W.C.

EXAMINATIONS BY MASS MINIATURE RADIOGRAPHY

The Ministry of Health has been asked to arrange that in all cases where persons are examined by mass miniature radiography, and the taking of a full-size skiagram is subsequently found to be necessary, the findings, positive or negative, will be communicated to the person's own doctor.

NATIONAL EYE SERVICE (N.O.T.B.)

The Insurance Acts Committee strongly endorses the appeal recently made to Panel Committees by the National Ophthalmic Treatment Board for more support for the service it provides, which is generally known as the "National Eye Service." This service was established in 1929 to provide insured persons with an ophthalmic medical examination and any necessary spectacles at a cost well within their means, and is available to all who are granted ophthalmic benefit by their approved societies. In view of the probability that the present arrangements for ophthalmic benefit will continue in many areas for some time after the commencement of the proposed National Health Service, it is hoped that general practitioners will encourage their insured patients to use the National Eye Service. The Head Office of the N.O.T.B., Tavistock House, Tavistock Square, London, W.C.1, will be glad to send full particulars of the service to any medical practitioner.

PURCHASE TAX ON DRUGS, INSTRUMENTS, AND CARS

The 1945 Annual Conference asked that the purchase tax be removed from all doctors' legitimate prescriptions, drugs ordered in bulk for dispensing, surgical instruments, and motor cars. This question was taken up with the Treasury by the Council of the B.M.A., but without success. The view of the Treasury is that there is no provision in the law which would enable goods subject to purchase tax to be exempted from tax on the ground that they have been sold to particular persons or are to be used for a particular purpose. If an exception of this kind were made it would be impossible to draw a line. It has accordingly been regarded as an essential principle of the tax that there should be no classes of consumers privileged to buy chargeable goods free of tax, and in these circumstances the Treasury regretted that it was not possible to give doctors any relief from purchase tax.

NATIONAL INSURANCE DEFENCE TRUST

The Balance Sheet and Statement of Expenditure and Income of the Trust for the year ending December 31, 1945, are being sent to every Panel Committee.

An appeal has been made to every Panel Committee that is not already doing so to take immediate action to implement the Trustees' decision to increase the objective amount of the fund to one million pounds. The Trustees have also asked every Panel Committee to undertake to make available to the Trust, on demand, all the funds at its disposal over and above the amount required for current administrative expenditure.

Emergency Guarantee Fund

The establishment by the Council of the B.M.A. of an Emergency Guarantee Fund should, by now, be known to every medical practitioner in the country. The Fund came into being as the result of proposals by the Trustees of the N.I.D.T., who had been giving consideration to the best method of building up a fund to be used if the Government proposals for a National Health Service proved unacceptable to the profession and if the Council of the B.M.A. decided to recommend practitioners not to accept service.

In 1942 it was decided that the objective of the N.I.D.T. should be one million pounds. But it was realized that, at the present rate of progress, it was likely to be many years before this amount was reached. At present the Trust Fund amounts to just over £300,000 and it was thought that insurance practitioners should not be asked to do more without a corresponding appeal to the whole profession. So the question of a fund to which the whole profession should be asked to contribute was raised.

On the recommendation of the Trustees, through the Insurance Acts Committee, the Council decided in February:

(a) That an Emergency Guarantee Fund be established for the whole of the medical profession;

(b) that the proposed Emergency Guarantee Fund be composed of pre-determined contributions from the British Medical Association and the National Insurance Defence Trust, together with the amounts guaranteed by individual members of the profession;

(c) that the amounts so guaranteed be called in only on the decision of the Council;

(d) that the unexpended portion of the total Fund be refunded to the B.M.A., the N.I.D.T., and individual guarantors in proportion to the amount contributed;

(e) that each individual member of the profession be asked to guarantee a minimum contribution of £25.

Under (b) the Council of the B.M.A. and the Trustees of the N.I.D.T. have each guaranteed an initial amount of £100,000. The resolution of the Special Conference on April 30, that the N.I.D.T. guarantee should be increased to £200,000, has been noted.

The Emergency Guarantee Fund will be administered by seventeen Trustees, representative of the Council of the B.M.A., the N.I.D.T., and the Negotiating Committee. Eleven of the seventeen are Trustees of the N.I.D.T. The whole of the administrative expenditure will be borne equally by the B.M.A. and the N.I.D.T.

The fund will be in two parts:

Part A.—To be used in any way which the Trustees deem advisable in the interests of the profession, where the Government plans are considered to conflict with those interests.

Part B.—To be used for all the purposes of Part A and, in addition, as far as funds permit, at the discretion of the Trustees to afford help to practitioners who suffer hardship as a result of their loyalty to the cause of the profession.

The B.M.A.'s guarantee is to Part A, as the Association is debarred by its constitution from contributing to Part B.

SCOTLAND

This particular section deals with matters which are of a purely domestic Scottish nature and which have not been referred to in the preceding paragraphs, or upon which action in England and Wales differs from that taken in Scotland.

Chairman and Deputy Chairman

Dr. J. F. Lambie (Glasgow) and Dr. A. F. Wilkie Millar (Edinburgh) were reappointed Chairman and Deputy Chairman of the Insurance Acts Scottish Subcommittee respectively for session 1945-6.

Advisory Distribution Committee of the Department of Health

The following were nominated as representatives of the Insurance Acts Subcommittee on the Advisory Distribution Committee: Dr. J. F. Lambie, Dr. A. F. Wilkie Millar, Dr. Robert Bruce, and Dr. R. W. Craig, Scottish Secretary.

Medical Advisory Committee

The Department of Health was informed that all members of the Insurance Acts Subcommittee would be available for service on Medical Advisory Committees constituted under the Medical Benefit Regulations (Scotland), 1938.

Rural Practitioners Subcommittee

The Rural Practitioners Subcommittee was reconstituted, with Dr. Robert Bruce (Aberdeenshire) as Chairman.

The main business dealt with by the Rural Practitioners Subcommittee was the remuneration of dispensing doctors in Scotland, in view of the increase given to dispensing doctors in England and Wales. Correspondence with the Department of Health for Scotland on the subject was considered and there-

after it was resolved that approval be given to the suggestion that an increase of 4d. per person be made in respect of 1946 instead of 1d. per person in 1945 and 3d. in 1946. The question of a Scottish capitation fee for dispensing doctors in place of the existing areal arrangement is at present under consideration.

Consideration was also given to the type of Health Centre likely to prove most useful in rural areas. The views of rural practitioners on the matter are being obtained. The Subcommittee noted with satisfaction the opinion expressed in paragraph 16 of the Report of the Inter-Departmental Committee on the Remuneration of General Practitioners regarding the average income of rural and urban practices, and agreed that the various mileage schemes of Panel Committees in Scotland be examined.

References to Tuberculosis Officers

The statement in the Annual Report of the Insurance Acts Committee for 1945 was considered. It was agreed to express the opinion that the Scottish Subcommittee was quite satisfied with the present position in Scotland.

Scottish Scheme for the Protection of Practices of Absentee Practitioners

Two joint meetings of representatives of the Insurance Acts Subcommittee, of the Scottish Association of Insurance Committees, and of the Department of Health were held when the recommendations to be made to the Department of Health regarding the amendments of Regulation 17 of the Medical Benefit Regulations (Scotland), 1938, and the Amendments of the Distribution and Allocation Schemes were considered. These amendments were necessary in view of the following provision in the Model Scheme for Scotland:

"At an agreed date after the end of the emergency the Insurance Committee shall issue blank Medical Cards to all persons whose names do not appear on the closed list of an insurance practitioner, in order that a fresh selection of practitioner be made."

On Dec. 11, 1945, a circular was issued to the Secretaries of Panel Committees in Scotland setting forth the agreed procedure.

Proposal for a National Health Service for Scotland

At a meeting held on Nov. 9, 1945, the Subcommittee considered the findings of the Special Scottish Representative Meeting held in June, 1945, in relation to the proposed National Health Service for Scotland. A document setting forth the main decisions of the various Committees of the Association in Scotland and other interested bodies was submitted and discussed. In general the Subcommittee agreed with the views expressed by the Scottish Committee.

At a meeting held on April 11, 1946, the Report of the Council of the B.M.A. on the Government's National Health Service Bill was considered, including the recommendations of the Insurance Acts Committee there anent. The Subcommittee, by a large majority, decided that the right to buy and sell practices be retained—that remuneration should be by capitation fees, and that the effective distribution of doctors should be secured by means of attraction and not by direction. In general, the terms of the report of the Council were approved.

Maternity Services (Scotland) Act, 1937

It was reported that the Department of Health had asked for the views of the Scottish Committee as to whether an insured woman applying for services under the Act should be required, as hitherto, to select her insurance doctor if he had agreed to render services under the Scheme. It was further reported that the Scottish Committee had expressed the view that an insured woman should have free choice of doctor, but that the opinion of the Insurance Acts Subcommittee be obtained. The Subcommittee endorsed the opinion of the Scottish Committee.

Estimated Number of Insured Persons in Scotland

The Subcommittee is informed that the number of insured persons in Scotland for whom payment has been made in respect of medical benefit for 1945 was 2,052,000. This was an addition of 44,000 to the provisional estimate of 2,008,000.

HEARD AT HEADQUARTERS

Full Calendar

After a brief interval for staff holidays and for taking break after the Annual Representative Meeting, Headquarters is piling up a busy time-table. During October the sessions of committees seem to be almost continuous. In addition to a special meeting of the Council in that month and the annual conference of Local Medical and Panel Committees, no fewer than fourteen standing committees of the Association are to meet as well as three group committees, six special committees, and two liaison committees. Liaison committees or joint committees with other organizations are becoming an important feature of headquarters activities. At present there are four of them, the other partners being respectively the Trades Union Congress, the British Hospitals Association, the Royal College of Nursing, and the Pharmaceutical Society. In addition to all these committees which have their dates well fixed in advance there are six or seven others in the offing whose meetings are arranged as required. All the indications point to a year of unprecedented medico-political activity. The direction which such activity may take is, of course, still uncertain. The turn of events may bring less or more work than is a present forecast, but most probably more. But Headquarters is in good heart and shape, and the Secretariat of the Association has been enlarged not a moment too soon.

Doctors' New Cars

It is distressing to receive from the British Motor Trade Association a complaint that some doctors—it is to be hoped the number is very small—have bought new cars which they do not need and have sold them again at inflated prices. The general body of doctors have enough difficulties on their hands in these days in getting and maintaining cars for their ordinary professional use without having the pitch queered for them by profiteers of this description within their own ranks. The car manufacturers and distributors, ever since the abolition of the Government licence system, have done their best to ensure that the legitimate demands of doctors are met as expeditiously as possible, but if doctors make use of their professional position to get priority deliveries of new cars which they do not need and do not intend to use, the result is to feed the black market, to maintain present inflationary tendencies, to add to the difficulties particularly of practitioners recently demobilized from the Forces, and to cast suspicion upon the whole profession. On a slightly less reprehensible in this present time of scarcity is the action of the doctor who obtains priority delivery of a new car when he already has a car which is reasonably roadworthy. The British Motor Trade Association states that it has brought in a requirement that all purchasers of new cars shall sign an undertaking not to dispose of them for six months. This sounds reasonable enough, and the assurance is repeated that the manufacturers and traders will do their utmost to get the earliest possible deliveries to doctors genuinely requiring new cars.

REMUNERATION OF DENTAL PRACTITIONERS

The Minister of Health and the Secretary of State for Scotland have appointed a committee of nine members, including four dentists, to recommend "what ought to be the range of total professional income of a registered dental practitioner in any publicly organized service of general dental practice." The full terms of reference are similar to those of the committee, of which Sir Will Spens is chairman, which has recently submitted a report on the remuneration of general medical practitioners (Cmd. 6180), are "to consider after obtaining whatever information and evidence it thinks fit what ought to be the range of total professional income of a registered dental practitioner in any publicly organized service of general dental practice; to consider this with due regard to what have been the normal financial expectations of general dental practice in the past, and to the desirability of maintaining in the future the proper social and economic status of general dental practice and its power to attract a suitable type of recruit to the profession and to make recommendations."

The Minister of Health has written to the chairman of the committee, Sir Will Spens, regarding the interpretation of the terms of reference. It had been suggested that the inclusion of the word

with due regard to what have been the normal financial expectations of general dental practice in the past" might in some way and the committee to base their recommendations on the past earnings of dentists. On this the Minister writes: "I can assure you—though I know you already fully understand the position—that any such conclusion is wholly mistaken. It is obvious that in quiring into this question of remuneration the committee would have to ascertain what dentists have, in fact, been earning in the past, and the exclusion of the words to which I have referred would only serve to throw doubt on this. But that would not mean that making their recommendations for the future they were in any way limited by their knowledge of what dentists have been earning in the past. As to this the terms of reference make it clear that the committee would have to have regard to the desirability of maintaining in the future the proper social and economic status of general dental practice and its power to attract a suitable type of recruit to the profession and it would be wholly a matter for the committee to say what, in their view, the remuneration of dentists should be in order to achieve these objects. As you know, words similar to the words in question have already appeared in the terms of reference of the committee over which you also presided, which inquired into the remuneration of general medical practitioners; and I think you will agree that that committee did not feel themselves limited in any way by the words."

MR. BEVAN ON THE HEALTH BILL

The annual luncheon of the Society of Medical Officers of Health was held in London on Sept. 20, the President, Prof. Johnstone Jervis, in the chair. The principal guest was the Minister of Health, the Rt. Hon. Aneurin Bevan.

Mr. BEVAN, in proposing the health of the Society, said that he would not be doing justice to his opportunity if he did not take advantage of the occasion to pay, on behalf of his Ministry, a very deep and sincere tribute to the work of the medical officers of health in Great Britain during the years of his war. They had done a most remarkable administrative job. He did not wish to apportion any awards for the comparatively good state of the nation's health, but it was an astonishing fact, and a tribute to all who had contributed towards it, that we were more immune from epidemics than at the end of the 1914-18 war.

The National Health Scheme

The House of Commons, Mr. Bevan continued, had passed the Health Services Bill with its main structure unaltered, though there had been some modifications in detail—a number of improvements made at the suggestion of colleagues in the House of Commons and of those representatives of the medical profession "whom I met from time to time in very amiable circumstances in the course of the passage of the Bill." He must not be too optimistic, because it had still to go to the House of Lords, and a number of very eminent persons were ready to pounce upon it there, but he did not anticipate any important alteration in the main principles. It would be unfortunate if a Bill of this sort should be the occasion for any misunderstanding or friction between the two Houses, and he was convinced that the House of Commons, having passed the Bill with its main structure unaltered, could look for the same co-operation on this very important measure as it had received on every measure in the course of the last twelve months.

When the Bill became law the main task would begin, the task of the administrators, which would be the harder task, that of clothing the structure with flesh in order to make it the best health service in the world. This would require the energies of the medical profession and not least those of medical officers of health. "The controversy has not completely died down, the armies are still arrayed on the battlefield, but they are becoming, I think, increasingly listless, convinced that the issue has really been determined, and that all we need do now is to get round the peace conference table with a little more fertility than is being achieved in other places." It was necessary to draft regulations, and he frankly confessed that it would be impossible to frame the regulations effectively and to administer them properly without the co-operation of the representative organizations of the medical profession in

all its branches. Therefore he was hoping that when the main battle had been determined, and when the representatives of the people had made up their minds what they wanted to do, all loyal citizens would co-operate in carrying out the will of the people so expressed. Any other course would spell anarchy and division, and there were too many urgent tasks awaiting them at the moment and for some time to come to allow them to fritter away their energies in internecine strife.

The main criticisms levelled against the scheme were to some extent contradictory, Mr. Bevan continued. A great publicist. "A well-known friend of the medical profession," had been stating that in his opinion the scheme provided far too much self-government for the doctors and he thought it disastrous that so conservatively minded a profession should be entrusted with so much self-government of its own affairs. Another critic, who was a medical politician, took the opposite view and said that the whole scheme made the Minister of Health a complete tyrant and that the doctors had no effective say at all in the management of their profession. "You can take one of those points of view—indeed, I am quite satisfied from what I have seen in the *British Medical Journal* that you can take both." It had been his purpose to follow with fidelity the principle laid down by Lord Dawson of Penn—namely, to create an apparatus of medicine, and then to leave the profession to exercise it in freedom and independence. It was for "us" to decide ultimately what the apparatus should be, but certainly they would be overstepping the frontiers of their rights if they attempted to interfere, to guide, or even to advise as to how members of the profession should use that apparatus when it was put in their hands.

"We are facing a very critical year. As soon as the Bill becomes law we have to face the task of carrying it out so that the whole machine will be ready to come into operation by April 1, 1948. It is a year of hard work. It is our intention to try to use, so far as they will allow themselves to be used, all the vast body of health workers who have built up such a splendid tradition. We do not want to discard in any way the services of those who have accumulated so much experience. I am deeply conscious of the fact that one of the great dangers of a Government service is over-centralization, and the wider the decentralization we can bring about the better for everybody. Therefore our first task will be to get the regional organizations established and then to get the management committees set up. Then, with the co-operation of the medical profession, we hope to get the medical councils established in the districts for the proper organization and supervision of the services."

The PRESIDENT, in response, said that they had admired the way in which the Minister had piloted this measure and was bringing it to port. To say that the measure was perfect would be an appraisal beyond its merits, but it was incontestably the greatest thing that had been done in social legislation in this or in any other country. The Society felt that the measure should have a fair chance to justify itself. There was nothing to be gained by adopting an unfriendly or hostile attitude towards it, and so far as he and his colleagues were concerned they might be relied upon to play the part allotted to them in an earnest desire to carry it to a successful issue. Prof. Jervis added that he himself had spent thirty years in the Local Government service, and next year he "laid down his tools" and went into obscurity. But before he went, in that gathering of friends and colleagues, he wanted to pay tribute to a very great British institution—Local Government. If the health services of this country had attained a high degree of perfection the credit was in great measure due to the initiative, enterprise, and hard work of local authorities. Local Government was the custodian of democracy. It was because of this that he deplored the present tendency of Government Departments to encroach upon the province and powers of these authorities.

Dentists throughout Great Britain are being advised by the Joint Advisory Dental Council to tell insured patients that their "dental letters" cannot be accepted, and that no contract can be entered into with the Government or Approved Societies, but that patients can be treated privately—on the scale of fees recommended by the Council which has been rejected by the Ministry of National Insurance. The Joint Advisory Dental Council on Sept. 13 announced almost unanimous support from the dentists in 26 London boroughs of its policy in the dispute over the new scale of fees payable under the National Health Insurance Acts.

Correspondence

Freedom and Financial Security

SIR,—To an inarticulate onlooker at various meetings and discussions, and after assiduously reading the voluminous correspondence appearing in the *Journal*, it is becoming abundantly clear that out of the welter of proposals, resolutions, etc., nothing has crystallized which will command universal support, so presenting our somewhat autocratic Minister of Health with a united front, and a determination that a more accommodating spirit is required if he is to enlist the willing co-operation of those whom he is at present coercing.

Should Mr. Bevan be so unwise as to offer an inadequate salary or capitation fee, then our ranks would be closed. This is the only issue on which we are united, but our astute Minister has no intention of falling into the error of promoting such a unity. It is likely that the initial remuneration will be up to expectations—in other words, the bait will be attractive enough for the other unpleasant features of the scheme to be swallowed, hook, line, and sinker.

The profession, whether we like to think so or not, is essentially concerned with making as good a living as possible out of its ministrations to ailing humanity. Those of us who cherish the thoughts of professional freedom, and of a way of life, will inevitably fall into line with our more materialistic brethren, justifying our action on the score of domestic commitments and other financial burdens which general practitioners find themselves saddled with. The élite among us may prefer to remain outside the scheme, feeling sure that their superior abilities will command a ready market for their services.

At this critical juncture we should be sufficiently frank with ourselves to admit that, however much we may think of professional freedom and independence, financial security is the only plank on which we will make a stand. It then becomes necessary to add that if we will not fight for the things we believe in, then quite properly we suffer the fate of those who, when the occasion arises, fail to adopt this manly expression of their convictions.—I am, etc.,

Blakeney, Glos.

J. M. ASHTON.

Tyres for Doctors' Cars

SIR,—Reading the correspondence in the *Journal* makes me very much aware of the difficulties placed in the way of the doctor by the present Government with its many restrictions—and despite its dissatisfaction with the country's existing medical arrangements. In my own case the difficulty is the inability to obtain tyres for my car. My present ones are nine years old and have lasted so long because I passed nearly six years of my medical career in the Services. They are now down to the canvas and are a danger, for they may burst any time. I applied to the petrol control officer of my district for the necessary form of application for tyres, and hearing nothing for three weeks I telephoned him and eventually the form arrived. This was completed and handed in to my garage, and I have been waiting nearly five weeks but still no tyres have arrived; either can I be given any date when I may expect them. I am delayed almost daily, due to punctures caused by the sharp flints on the country roads that I am compelled to use in this type of practice, and my patients suffer in consequence.

What is the use of all these priority forms, permits, etc., if the material isn't available? I am quite ready to pay for my tyres. Can't the Government do something really helpful for the frustrated doctor and see that he gets his tyres when he needs them, and help and not handicap him?—I am, etc.,

COUNTRY DOCTOR.

A deputation from the National Veterinary Medical Association, representing over 1,000 members throughout the country, visited the Ministry of Agriculture on Sept. 20 to oppose the Ministry's scales of pay for technical officers of its animal health division. The Association holds that the salary of the Ministry's chief veterinary officer should be similar to that of the chief medical officer of the Ministry of Health, and that the pay of other Government grades should be fixed accordingly.

Association Notices

Branch and Division Meetings to be Held

WILTS BRANCH

At the Mental Hospital, Devizes, Sunday, Sept. 29, 3 p.m.
Agenda: Discussion on new Insurance Capitation Fee, etc.

POSTGRADUATE NEWS

The Fellowship of Medicine announces: (1) Week-end course Ear, Nose, and Throat Diseases (for general practitioners) all day Saturday and Sunday, Sept. 28 and 29, at Metropolitan Ear, Nose and Throat Hospital; (2) course in gynaecology, daily, Oct. 7 to 11 at Samaritan and Soho Hospital; (3) week-end course in medicine and surgery (for general practitioners), all day Saturday and Sunday Oct. 12 and 13, at Royal Hospital, Richmond, Surrey; (4) Neurosurgery (suitable for F.R.C.S. (Final) candidates), lectures on Mondays, Tuesdays, and Wednesdays, at 2.30 p.m. from Oct. 20 to 29, at West End Hospital for Nervous Diseases.

The Edinburgh Postgraduate Board for Medicine has arranged series of open lectures on subjects of wide biological significance to be held in the West Medical Theatre of Edinburgh Royal Infirmary on Tuesdays, Oct. 15 and 29, Nov. 12 and 26, and Dec. 10, at 5 p.m. The lectures are being held in connexion with the postgraduate courses in medicine and surgery and all graduates and students are invited.

WEEKLY POSTGRADUATE DIARY

BLACKPOOL: VICTORIA HOSPITAL.—Thurs., 8 p.m. Mr. Lamont: Common Disabilities of the Shoulder Joint.

EDINBURGH POSTGRADUATE LECTURES.—At West Medical Theatre Edinburgh Royal Infirmary, Thurs., 4.30 p.m. Mr. J. R. Cameron: Congenital Anomalies of the Kidney.

GLASGOW UNIVERSITY: DEPARTMENT OF OPHTHALMOLOGY.—Wed. 8 p.m. Mr. John Foster: An Ophthalmic Tour of Switzerland.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Orthopaedics.—Tues., 8.30 p.m., Presidential Address by Mr. V. H. Ellis: Injuries of the Cervical Spine.

Section of History of Medicine.—Wed., 2.30 p.m., Presidential Address by Sir Arthur MacNalty: The Evolution of English Preventive Medicine.

Section of Neurology.—Thurs., 8 p.m., Presidential Address by Dr. Douglas McAlpine: The Problem of Disseminated Sclerosis.

THE LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C., Tues., 5 p.m. Dr. J. E. M. Wigley: Eczema. Thurs., 5 p.m. Dr. G. Bamber: The Misuse of Antiseptics and other Medicaments in Dermatology.

APPOINTMENTS

ROYAL SHEFFIELD INFIRMARY AND HOSPITAL.—Biochemist, A. Jordan, M.B. Honorary appointments. Physicians, Profs. C. H. Stuart-Harris, M.D. F.R.C.P., and E. J. Wayne, M.D. F.R.C.P. Orthopaedic Surgeon, A. Dornan, F.R.C.S. Ophthalmic Surgeon, Edith Hatherley, M.B., D.O.M.S. Dermatologist, I. B. Sneddon, M.B., M.R.C.P. Radiologist, T. Lodge, M.B. F.R.C. Surgeon to Ear, Nose, and Throat Department, J. D. Gray, F.R.C.S.

RUSSELL, P. M. G., F.R.C.S., M.R.C.O.G., Surgeon in charge Obstetric and Gynaecological Department, Royal Devon and Exeter Hospital.

STOKOE, J., M.D., D.P.H., Medical Officer of Health, Borough of Scarborough.

BIRTHS, MARRIAGES, AND DEATHS

The charge for an insertion under this head is 10s. 6d. for 18 words or less. Extra words 3s. 6d. for each six or less. Payment should be forwarded with the notice, authenticated by the name and permanent address of the sender and should reach the Advertisement Manager not later than first post Monday morning.

BIRTHS

AIDNEY.—On Sept. 17, 1946, at Queen Elizabeth Hospital, Birmingham: Constance Aidney, M.B., Ch.B. (née Hughes), wife of J. Denis Aidney, a daughter—Diane Lisbeth.

ANDERSON.—On Sept. 13, 1946, to Doris (née Twiddy, S.R.N., S.C.M.), wife of Dr. C. A. Anderson, 36 Belmont Road, Uxbridge, Middlesex, a daughter.

COLLINS.—On August 23, 1946, at Nelson, New Zealand, to Joan (née Williams) M.B., Ch.B., wife of H. C. Collins, a daughter.

LOW.—On Sept. 20, 1946, at Windsor, to Wendy, wife of Dr. W. J. Low, Flackwell Heath, Bucks, a son.

SILCOCK.—On Sept. 16, 1946, at the Radcliffe Infirmary, Oxford, to Kay (née Carson), wife of Dr. A. R. Silcock, a daughter—Carolyn Mary.

MARRIAGE

ROBERTS—HOLLOWAY.—On Sept. 2, 1946, at Worcester, Keith Danford Roberts, M.B., M.R.C.S., to Margaret Evelyn Holloway, S.R.N.

The twenty-ninth annual meeting of the National Association of Insurance Committees will be held in the Dome, Brighton, on Oct. 3 and 4. On the second day Mr. C. W. Key, M.P., Parliamentary Secretary to the Ministry of Health, will give an address.

LONDON SATURDAY OCTOBER 5 1946

MEDICAL EXPERIENCES IN JAPANESE CAPTIVITY

BY

E. E. DUNLOP, M.S., F.R.C.S., Lieut.-Col., A.A.M.C.

[WITH PHOTOGRAPHURE PLATE]

The fruits of experience as prisoners of war in Japanese hands, though abundant, were exceedingly bitter. Herculean tasks were enforced upon semi-starved and enfeebled captives—for example, the construction of the Burma-Siam railway by slave labour with primitive hand tools. To medical personnel fell the scarcely less arduous task of clearing the Augean stables of sickness. The crude slave-hovels used for the accommodation of prisoners were euphemistically termed "hospitals" when allotted to the sick, and were provided with some slender medical staff. During the days of darkest savagery they were little more than crowded pest-houses where sick were conveniently segregated, though by no means allowed to die in peace.

I have been asked to record briefly some salient impressions of three and a half years of imprisonment in Java and Siam, involving prisoner-of-war command of a number of camps and hospitals, including railway construction camps. The medical problems of the scattered prisoner-of-war groups in the Far East, and the struggles of the medical services against great odds, are of historical interest. The circumstances militated against research or far-reaching discovery but sharpened the unaided senses to greater clinical acuity and necessitated resource and ingenuity of a high degree. It is obvious that many prisoners of war will suffer for the remainder of their lives from disabilities related to their grim ordeal. Those who witnessed their fortitude and unconquerable spirit under conditions of great suffering, slow starvation, and physical wretchedness hope that their disabilities will be fully comprehended and will receive generous consideration.

Conquest of Java

In Java, as in other conquered regions, medical personnel together with sick and wounded shared in the general programme of attrition designed to teach a sharp lesson to "criminals" and "rabble" who had dared to oppose the Japanese Army. All the inmates of an Allied general hospital under my command were ejected at a few hours' notice, and the majority forcibly marched to a fantastically overcrowded native gaol with negligible medical arrangements, where calculated humiliation, gross under-feeding, and savage regimentation were the daily routine.

Only a few medical stores, widely dispersed and concealed, escaped confiscation. Defiance of international conventions was emphasized by the confiscation of Red Cross brassards, along with badges of rank, unit or service ribbons, decorations, etc. Under compulsion all Red Cross markings were obliterated. Mass violence and beatings and some untidy public executions enforced obedience, under vigorous protest. Uniform clipping of the hair to the scalp was required, and the extravagant mass "salutations" enforced by the humblest of Japanese soldiers produced spectacles not devoid of Gilbertian humour. Medical officers and padres spent considerable time and energy in the task of instructing in Japanese drill and ceremony. There was some alleviation of the harshness of treatment in the British P.O.W. camp under my administration at Bandoeng, where for a few months the prisoners carried on highly organized educational and recreational activity in the teeth of difficulties and misunderstandings.

Malnutrition and deficiency diseases were rife within six months, pellagra being excessively common and associated in approximately one-third of all troops with distressing burning of the feet. The ration at this time amounted to about 2,000 calories daily. While much more adequate than that in some later camps, it consisted largely of low-grade rice or dried potatoes, and was thus markedly deficient in protein, fats, and vitamins, especially of the B complex. The Japanese paid little heed to protests, carefully documented requests, or demonstrations of cases, but following the official acceptance of the captives as "prisoners of war" meagre pay for work was introduced. This pay together with some fortunate clandestine negotiation for money on credit enabled us to augment the diet of the sick with purchased foodstuffs according to need.

The Burma-Siam Railway

Late in 1942 the movement of Allied prisoners to Lower Burma and Siam commenced. Soon some 60,000 captives and a larger force of Asiatic coolies were given the gigantic task of cleaving a railway through 400 kilometres of jungle-clothed mountains and oppressive valleys between Thanbyuzayat (Burma) and Bampton (Siam). By the end of 1943 the main task was completed by the enfeebled remnant of the decimated force. Some 15,000 prisoners together with uncounted scores of thousands of Asiatic coolies had perished. While this major tragedy was largely due to calculated official brutality and inhumanity, Japanese medical officers contributed in lending what zeal they possessed to the support of medical enormity in search of further labourers, rather than in a co-ordinated medical plan of evacuation, hospital services, and supply of medical stores.

Indiscriminate treatment of prisoners led to my being placed in command of a working force of Java captives transferred as packed human freight in the holds of a tramp to Singapore, and subsequently by rail for four days in box-trucks to Siam, where in due course they marched into the Konyu-Hintok section of the line in dense jungle about the Kwa-Noi river. Some six months of command of working camps mixed with endless medical work and peripatetic surgery was followed by experience of command of jungle hospitals, including Kinsayok, Tarsau, and Chungkai, before I was transferred in June, 1944, with large numbers of sick of the Siam force to Nakom Patom. There I enjoyed the privilege of working under Lieut.-Col. A. E. Coates, A.A.M.C., as O.C. surgical section of this large hospital, devoted to men still broken in health by the railway construction in Burma and Siam. The grimmest battle for the lives of men had already been fought in the crudity of jungle areas, and the attitude of the Japanese left little doubt that improved conditions bore some relationship to the changed state of the war and to world knowledge of the treatment of prisoners.

Working Camps

During railway construction men worked under savage pressure up to sixteen hours a day for months without rest, so that they rarely saw their squalid bums and tents in daylight. Amid thorny jungle and rotting corruption, with ceaseless monsoon rain lashing their bodies and soaking their miserable accommodation, large numbers were soon bootless, with practically no bedding.

and reduced to rags about their loins. The heat was in general excessive, and well-nigh intolerable to bare feet in rock cuttings, but the greatest load on men's spirits was the pouring monsoon rain, converting the whole area into a quagmire of evil-smelling mud.

Pellagra diarrhoea, irritable bladders, and massed overcrowding interrupted rest, and the urge was often uncontrollable as men floundered out into darkness, rain, and mud. Hunger, food deficiency diseases, malaria, dysentery, ulcers, and skin sepsis, and extreme exhaustion were woven into a dull fabric of suffering rent here and there by sharp outbreaks of cholera. Whatever reserves of physical strength or spirit a man might possess were in the long run exploited, so that the stronger suffered longer, only to pay the same relentless tribute in loss of life and broken health.

Apart from some capricious inoculation measures, preventive medicine, hygiene, and sanitation were negligible. Men and tools were grudgingly spared for the most primitive sanitary measures. Such materials as antimalarial oil or chloride of lime were absent or pathetically scarce. Often there were insufficient containers to supply boiled water. Until the belated supply of limited American Red Cross stores in mid-1944, medical supplies other than quinine were farcical. A typical monthly issue for a thousand men, mostly sick, consisted of 6 to 12 bandages, a small piece of gauze or cloth, 1 or 2 ounces of spirit or iodine solution, and a few dozen assorted tablets of dubious value. Non-expendable stores such as instruments and ward equipment, though freely confiscated in the early months, were afterwards only possessed by cunning or ingenuity, since no issues were made. Allied medical personnel were distributed with scant regard to either incidence of sickness or qualifications on a scale of about 1% of strength—doctors and orderlies combined—for all purposes. Where by faulty distribution the number exceeded this slender provision, as in Konyu and Hintok camps, they were compelled to do routine manual work and the sick were deprived of their services.

"Most Shameful Deed"

As the working force deteriorated under semi-starvation, diseases, and illimitable exhaustion, ferocious pressure was exerted to secure from sick and dying men increased fortitude in the Japanese Imperial cause. As sickness was regarded as a crime, the sick were given no pay and a reduced ration scale. (Col. Nakomura on assuming command of prisoners of war in Siam in June, 1943: "Those who fail in charge by lack of health is regarded in Japanese Army as most shameful deed.")

Relentless insistence upon fixed figures of workmen daily, if defied, led to the sick being turned out of hospital with indiscriminate violence. Sick parades were endless, since the wretched condition of the men required daily assessment and comparison. They dragged in up to midnight or beyond, and attendance was again needed at works parades before dawn. Japanese N.C.O.s and privates frequently overruled medical officers and cut short argument with violence.

In the Hintok area works parades were a deplorable spectacle, featuring scores of men tottering with the support of sticks, or even being carried out bodily to meet fixed figures. Men unable to stand were carried, to work in a lying or sitting position. During the grimmer months of railway construction the sick were deliberately persecuted by works supervisors. For example, men with horribly festering bare feet were forced to work on sharp rocks or in thorny jungle hauling logs; disabling ulcers were struck or kicked; those collapsing were savagely handled; and sufferers from diarrhoea and dysentery were compelled to foul themselves working.

The engineer officer of this area, Lieut. Hirota, led his men in ferocity by personal example, and on occasion flogging of the sick was followed by their demise. Lieut. Osuki, P.O.W. camp commander, stated that he did not care if sick men died, since "working percentage better." Lieut.-Col. Ishii, in charge of 13,000 prisoners, when shown emaciated dysentery sufferers devoid of drugs, commented on the treatment by no food for two to three days with loud laughter and the retort: "In future no food one week, better!" The pungent protests of medical officers against these conditions need hardly be instanced. Capricious evacuations of sick were by casual hitch-hiking on passing lorries or barges. The weak supported or carried the

weaker. Frequently days were spent in transit with exposure and little food. Barges arrived at jungle hospitals with both the quick and the dead in the stench of gangrene and dysentery.

Jungle Hospitals

Typical of early base hospitals heroically evolved under the greatest difficulties in Burma were Thanbyuzayat, Lieut.-Col. T. Hamilton, A.A.M.C.; and 55-Kilo hospital, Lieut.-Col. A. E. Coates, A.A.M.C. In Siam, Tarsau, Lieut.-Col. W. G. Harvey, R.A.M.C.; Takannoun, Major T. M. Pemberton, R.A.M.C.; Chungkai, Majors Reed, R.A.M.C., D. Black, I.M.S., and Lieut.-Col. J. St. C. Barrett, R.A.M.C.; Kanburi, Lieut.-Col. J. Malcolm, R.A.M.C.; Tamarkan, Major A. A. Moon, A.A.M.C.; and Non Pladuk, Major Smythe, R.A.M.C.

The conditions at Tarsau and Chungkai hospitals at the time I was first associated with them are illustrative. Each contained a constant population of approximately 2,500 very sick men as a citadel within a jungle city of sickness. The sick lay massed together on bamboo staging in decrepit collapsing huts. Bedding and hospital utensils were largely non-existent. No instruments and very few medicines were supplied by the Japanese. Lack of tools, materials, and fit men combined with overcrowding to create a nauseating lack of hygiene. Bugs, lice, and almost universal scabies infection produced minor torments and florid skin sepsis. Men were too weak to keep themselves clean, and there were few orderlies, or even containers for water.

TABLE I.—Chungkai P.O.W. Hospital Statistics

Disease	1943			1944		
	Total Treated	Died	Case Mortality Rate %	Total Treated	Died	Case Mortality Rate %
Malaria	3,336	67	2.0	1,753	13	0.74
N.Y.D.	374	—	Nil	142	—	—
Bacillary dysentery ..	734	129	17.5	1,339	—	1.44
Amoebic dysentery ..	1,309	266	20.3	1,113	46	4.13
Enteritis	565	19	1.6	414	12	2.92
Cholera	134	54	40.3	8	—	—
Diphtheria	88	14	15.9	—	—	—
Lobar pneumonia ..	26	23	88.5	13	6	46.15
Bronchopneumonia ..	32	25	78.1	6	3	50.0
Bronchitis	32	—	Nil	47	—	—
Avitaminosis (mixed) ..	774	257	34.5	397	61	15.36
Pellagra	189	110	58.2	62	10	16.1
Beriberi	335	170	50.7	100	11	11.0
Tropical ulcer	1,353	37	2.7	1,129	—	—
Other skin diseases ..	851	—	Nil	674	—	—
All other diseases ..	1,496	89	5.9	795	24	3.02
Grand total ..	11,572	1,237	10.7	6,793	188	2.70

The condition of tropical ulcer patients was pitiable, and these wards stank of the hospital gangrene of pre-Listerian days. Rags, paper, leaves, and locally picked kapok and cotton were employed as dressings. The blowflies hanging in clouds about the patients produced maggot infections with far from benign effect. Dysentery and avitaminosis wards were scarcely less distressing. Some crude operating and pathological facilities had arisen from P.O.W. enterprise. With the easing in the intolerable pressure for workmen following the completion of the railway, more hands were available to help the sick. In the teeth of almost insuperable difficulties, these crude hospitals were equipped, financed, and carried on to signal triumphs almost entirely from P.O.W. resources. Discipline, supremely high morale, and the pooling of resources in foodstuffs, money, materials, and human ability were even more important than purely medical treatment. A duck's egg daily might be all that was needed to turn the scales of a man's life. Herculean labours improved sanitation and accommodation. Patients were trained as medical orderlies, others were employed in the mass production of improvised equipment, even if they were only able to whittle with a knife on their beds. Sick-welfare money from various national and unit sources was directed into a common pool, and used with the utmost economy in a planned series of standard special diets, or in the clandestine purchase of essential drugs from the Siamese. For example, at Chungkai from January to April of 1944 we raised 38,000 dollars from prisoners' meagre resources, largely from the officers' pay of 30 dollars a month. (On capitulation of the Japanese the rate of exchange was 60 dollars to one English

pound.) In addition, friendly sources outside contributed 3,000 dollars a month. Emetine, iodoform, and other drugs were obtained by the risky venture of selling Nipponese quinine. Emetine cost 35 dollars for 1 grain (65 mg.), and iodoform for tropical ulcers several hundred dollars a bottle.

The relationship of equipment to special problems was well illustrated by the great fall in septic cross-infection after the introduction of a rigid "forceps" technique, employing large irrigating cans and small portable sterilizers, made from the mess-tins of dead men and heated by charcoal stoves devised from biscuit tins and mud. Even this simple equipment was extremely hard to obtain; and the striking benefits of mass disinfection and scabies treatment involved stealing petrol drums to make steam disinfectors. Intensive surgical measures were employed to drain pus, remove sequestra, and graft raw areas; amputations were performed where necessary. The steep fall in mortality at this stage was most gratifying.

Nakom Patom P.O.W. Hospital

This huge hospital situated on the paddy-fields some twenty miles (32 km.) from Bangkok contained as many as 8,000 sick during its most active period. Little was provided for prisoners other than the buildings and some Red Cross stores, but with

ordinary experience as yaws and leprosy. The main diseases are shown in tabular form. Chungkai P.O.W. hospital statistics (Table I), kept by Major A. L. Dunlop, R.A.M.C., are self-explanatory. Where multiple diseases were present only the main disease on admission was recorded. Australian figures (Table II) are taken for my seven working camps, since the records I retain of other nationals are less complete. The average camp population from which the Australian casualties quoted were drawn was approximately 1,000. Usually two medical officers and six to eight medical orderlies were available.

Malaria

In the absence of adequate clothing, bedding, and mosquito nets, in jungle areas where there were debilitated troops and negligible larval and mosquito control, the disease was almost universal. B.T. infections predominated over M.T. and showed such phenomenal recurrence rates as twenty attacks in a year. Suppressive quinine in a dosage of 3 to 6 gr. (0.2 to 0.4 g.) daily in my experience was given too sporadically to have noticeable effect.

Blackwater fever was not common—e.g., a total of 17 cases at Nakom Patom among thousands of malarial subjects enduring repeated attacks. Cerebral malaria was not infrequent, and

TABLE II.—*Australian Patients Admitted to Author's Working-camp Hospitals June, 1942 to October, 1943*

Camp	Malaria	Dysentery	Enteritis	Cholera	Diphtheria	Pneumonia	Bronchitis	Avitaminosis and Malnutrition	Injuries	Tropical Ulcers	Other Skin Diseases	Other Diseases	Totals	Deaths

Deaths	—	10	—	63	—	1	—	3	1	—	—	5	83	—

Notes.—1. Most cases of enteritis were of pellagrous origin. 2. The figures bear little relationship to total disease, since almost all troops worked through illness, and malaria and pellagra were almost universal. 3. Where several diseases were coexistent only the principal one was recorded. 4. Avitaminosis and malnutrition column: 50% were serious pellagra cases, the remainder cases of protein oedema and beriberi. 5. The low death rate at this time was quite exceptional, and is in large measure due to the fact that most of these troops were seasoned Middle East veterans of very fine physique. Large numbers, however, died at a later date in base hospitals.

more static conditions, and comparatively greater material resources for improvisation, the scope of medical work was made to compare with that of a large civilian hospital. Had even the crude facilities of this hospital been made available at an earlier date, great loss of life might have been avoided. Pin-pricking regimentation and constant interference with medical officers and sick, day and night, made the work of the hospital very difficult, and parties of sick were constantly being transferred in the teeth of medical opposition.

Isolated parties transferred in this fashion were employed in railway maintenance, road construction, and bridge repair in areas harassed by Allied bombing, and some suffered terrible experiences recalling the tragic fate of "H" and "F" forces during railway construction. An epic story was a six-weeks march of 800 British soldiers for some 600 km. (375 miles) from Nakom Nyak to Pitsanloke carrying their sick on rice-sack stretchers. Due to the devoted work of the medical officers, Capt. C. J. Poh, S.S.U.F., and Capt. T. Brereton, A.A.M.C., only three died on the march.

Records and Statistics

All the diseases of the male adult were encountered, and in addition numerous tropical diseases, even those as remote from

with no ampoules of quinine suitable for injection, sterile solutions were made from any quinine available. I found Howards' 5-gr. tablets of quinine hydrochloride very effective given intravenously in a dosage of 10 gr. (0.65 g.).

Malnutrition and Avitaminosis

"Vitamins are luxuries," was the answer of a Japanese medical officer, Capt. Novosawa, to a request for an increase. Pellagra was the most common disorder, and exerted a sinister influence on the course of other diseases. The early symptoms of pellagra appeared after a few months of imprisonment—notably angular stomatitis, glossitis, pigmentary changes, and dry scaly skin. Scrotal dermatitis with erythema and loss of rugae rapidly progressed to exudation and scaly crusting. "Burning feet," much in evidence after six months, gave great distress at night, the sensation being most marked in the ball of the foot and passing forward to the toes. In some the legs and hands were affected. The circulation in the feet was excellent, but free sweating gave them a clammy feeling. The deep reflexes were hyperactive, and some patients had knee and ankle clonus. Rare cases progressed to spastic diplegia. Amblyopia was seen at the same time as the "burning feet," and occasionally both conditions occurred in the same case.

Later experience showed the rapid response of scrotal dermatitis and most mouth lesions to riboflavin, 6 to 8 mg. daily for a few days. Nicotinic acid or nikethamide was effective for other symptoms, except the amblyopia. In my experience the diarrhoea associated with pellagra was not very evident until the second year of prisoner-of-war life, when it became common and distressingly uncontrollable. Mental derangement was seldom marked, though in the terminal phase some cases showed extreme mental apathy and evinced difficulty in swallowing any food, particularly rice.

Nutritional oedema or famine oedema was excessively common, some soldiers becoming horribly bloated. In severe cases alimentary absorption seemed poor, and deterioration continued despite large numbers of eggs daily. Beriberi occurred in all forms, though in some instances it was confused with famine oedema. Scurvy and frank vitamin A deficiency were uncommon.

The basis of these disorders will be evident from the average ration recorded at Hintok camp in March, 1943. (This particular ration is by no means indicative of lower levels.)

Average issue per man per day: sugar 16 g., salt 10 g., fresh vegetables (mostly Chinese radish) 23 g., dried vegetables 6 g., meat 16.5 g., dried fish 26.5 g., oil of coconut 3 g., rice 600 g. (poor quality, some musty and almost uneatable).

Many sources of vitamins were tried in the absence of vitamin concentrates, but none was so effective as fresh foodstuffs obtained by money or credit. The whole question of a man's survival frequently hinged on the provision of money from prisoners' meagre resources, and on purchase facilities. Fresh ducks' eggs and the *katchang idjoe* bean (a lentil favoured by the Dutch) were excellent for all purposes. Meat was more expensive; yeast excellent but difficult to produce economically in concentrated form. Grass extracts were freely employed, but suitable grass was rare in the jungle. Jungle "spinach" was popular. The supply of ducks' eggs for purchase, always hazardous in the jungle, was a major consideration in sustaining life in Siam. Blood transfusions later became a valuable measure in the worst cases of malnutrition, and under all circumstances there was no dearth of volunteer donors.

Cholera

The severe outbreaks of cholera were due to squalid conditions and association with Asiatic coolies, who contaminated water supplies and camp areas. Water sterilization often presented great difficulties. The Japanese showed terror of the disease, and frequently compelled the patients to be attended in appallingly unsuitable jungle sites with little shelter—in the hope they would die quickly. One notorious case where a cholera sufferer was shot by Japanese order illustrates this attitude.

Typical cases showed dramatic prostration, with copious rice-water stools, vomiting, husky voice, cramps, rigging in the ears, weakness, and feebleness. As sterile saline and disinfectants were not supplied, many courageous improvisations were made, particularly for the replacement of fluids in the algid phase. Saline was prepared from kitchen salt and spring, river, or rain water distilled in curiously designed stills. In one instance a medical officer employed a drilled bamboo thorn as an improvised cannula, and on occasion the risk was taken of administering saline with boiled and not distilled water. The most severe epidemic I encountered was one with which Major E. L. Corlette, A.A.M.C., and I were concerned at Hintok, where in our own immediate camp of 1,000 men, 150 showed obvious infection, and there were 63 deaths. Hundreds of deaths occurred in the neighbourhood. The cases were nursed under leaking rags of tents, in an appalling morass in the jungle. Some early cases were given intraperitoneal saline injections of several pints. Three stills were hurriedly improvised from lengths of a stolen petrol pipe surrounded by bamboo jackets, and irrigated by water brought in bamboo pipes from a spring. Some 120 pints (68 l.) were produced and given daily through a number of continuous saline sets manufactured from such oddments as our stethoscopes, bamboo tubing, saki bottles, etc. In cases with extreme fluid loss as much as 20 pints (11 l.) were given in twenty-four hours. Saline was very effective in the algid phase, but numbers passed into the stage of reaction (typhoid state),

rosy flush, and fever, or succumbed to other illnesses related to their gross debility.

Hypertonic saline was seldom employed owing to the clinical facilities. Capt. J. Markovitch, R.A.M.C., reported favourably on the use of double-strength saline. I found potassium permanganate, in the usual 2-gr. (0.13 g.) dose a pill wrapped in a cigarette paper, did not give relief commensurate with the burning discomfort caused.

Dysentery

Despite the appalling mortality and morbidity caused by disease the Japanese refused to recognize its presence and compelled us to refer to it officially as "colitis," or still more vaguely as "other conditions." Amoebic dysentery predominated, but emetine and other specifics were not supplied by Japanese. The terrible severity of amoebic infections and great shortage of emetine presented problems dealt with in a separate paper (1946). Liver abscess was an infrequent complication, which under the circumstances required open drainage by the subcostal or transthoracic approach.

Tropical Ulcer

This disease was highly prevalent in jungle areas and famished fever-ridden subjects exposed to blows and trauma. A distressing feature was massive spreading gangrene with exacerbations of spread. Frequently the deep fascia was penetrated and there followed gross involvement of bone, joint, muscle, tendon, vessels, and nerves. The type of evacuation and the practice of flooding ill-equipped hovels with the patients were disastrous. The base hospital sections receiving them became cesspools of "hospital gangrene." Waves of violence spread about the wards, infecting other wounds—incisions for suppurative bursitis, septic scabetic lesions, healing ulcers.

Ulcers were often multiple; three men seen in association with Capt. J. McConachie, R.A.M.C., were dying in agony from large ulcers arising from minor skin lesions all over the body and limbs. The pain, of which I have had personal experience, was very severe and caused muscle spasm, so that the lower limb frequently contracted with flexed knee and dropped to the ground. Natural healing, where the outcome was favourable, took months to years, and often resulted in severe deformity. Most antiseptics were useless, and for effective action reagents were destructive to normal tissues—e.g., hyd. perchlor. solution 1 in 50, saturated solution of potassium permanganate, strong copper sulphate solution, pure phenol or lysol.

The best measure was removal of all gangrenous tissue by excision and curettage, followed by the application of pure phenol or lysol and a light sprinkle of iodoform powder. The latter was a specific for tropical infection, often effective even with such economy as 1 in 20 dilution. The distressing pain disappeared and the dressing could be left for days; the resulting granulating area was then skin-grafted. With this procedure early cases could be healed in a month without deformity. The Japanese did not supply iodoform, but it could be bought in small quantities at high prices from the Siamese. It was the most economical of all purchased drugs, and the sight of a man brought a glad smile to sufferers.

Many hundreds of men endured the agony of curettage of ulcers necessarily without anaesthesia. Necrosed tendon and muscle required wide incisions in fascial planes and formal excision. Huge sequestra were extracted when they loosened, some constituting the greater part of the shaft of the tibia. Nakom Patom sequestrectomy was accompanied by the "saucerizing" procedures. Amputation was often necessary to save life, and some patients begged for it, despite the cruel knives and butchers' saws employed. Immediate mortality rates were surprisingly good—e.g., under 10%—but there were associated gross nutritional disorders often evidenced by running diarrhoea and famine oedema. Further depletion of body protein occurred with the copious discharges. Ultimately about 50% of amputation cases succumbed, many of them after good healing. Blood transfusion was a valuable measure. When hostilities ceased, 170 amputation cases surviving at Nakom Patom, including two with bilateral amputations, were already provided with useful artificial limbs.

MEDICAL EXPERIENCES IN JAPANESE CAPTIVITY—E. E. DUNLOP

Physiotherapy Apparatus

Some hundreds of skin grafts in the hospitals with which I was associated showed gratifying results in healing and lessened deformity, compensating for great difficulties in arranging dressings and suitable firm pressure over graft areas. I found that light dust of iodoform powder over the graft area gave considerable protection against recurrence of tropical infection.

Scabies and Infected Skin Lesions

In some hospitals over 90% of the population had scabies, many with florid skin sepsis. Mass treatment by wards was required, using improvised steam disinfectors for personal effects. Sulphur was largely purchased in a crude form. A very economical suspension with a minimum of oil was made by means of ox bile.

The feet of workmen employed without boots and constantly in mud and water became cruelly inflamed with gross septic infection. Cure was difficult without rest.

General Points

Mental disorders were surprisingly infrequent, and neurosis uncommon among Anglo-Saxon prisoners. The hostility of the Japanese to the sick made their lot so unattractive that possibly a source of conflict was removed. Notwithstanding this fact, in well-led camps a heroic feature was the routine way men in the extremity of fatigue and debility lined up to take the place or bear the burden of those in worse case. A minor outbreak of hysterical palsies in the last year of imprisonment was predominantly among Netherlands East Indies soldiers. Suicide was uncommon and I personally know of only six cases. Possibly owing to lack of all privacy, and to the debilitating diet, sexual perversion was very inconspicuous. Though some men inevitably became morose and irritable, and quarrels arose, sanity, good humour, and optimism were predominant.

Ingenuously hidden wireless sets and news translations helped in sustaining morale, as did the organization of recreation, entertainment, and mental activities. Astonishing stage effects were obtained with rice matting, bamboos, rags of mosquito netting, etc., and symphonies were orchestrated from memory and played with impressive effect on instruments of great ingenuity. Fertile minds invented most diverting games. Formal religion appeared to have no enhanced appeal in camps of sickness and death. The maintenance of strict discipline was the greatest factor in preserving life and maintaining morale, and this was never questioned where officers set an example in unselfish devotion to duty.

Jungle Surgery

The Japanese with characteristic interest in the dramatic and sadistic appeared to find a surgical operation a "good show." Shortly after arriving in the dense jungle in the Konyu area I performed a successful night operation for a perforated duodenal ulcer—on a hurriedly constructed bamboo table, lit by a bonfire and a borrowed hurricane lamp. Following this event I was freely allowed to visit other camps to perform operations, and incidentally effect medical and other liaison. In these areas only emergency operations were performed, such as those for acute abdominal lesions; wounds, and gross sepsis, and usually in the open or under a large mosquito net. Many penetrating wounds were seen from brittle fragments of steel drills (e.g., necessitating excision of the eye), and some severe dynamiting injuries.

In the absence of strapping for extension, fractured femurs were best treated by driving the cleanest nail that could be found through the upper tibia. Thomas splints were devised by twisting wire, and pulleys and cords were manufactured. The Hamilton Russell type of extension was used on occasion. It was found that good healing usually occurred in abdominal wounds, using well-washed hands and no gloves. All instruments, along with such drapings as were available, were sterilized by boiling.

Lack of anaesthesia was the greatest difficulty, and it was necessary to perform most minor operations in its absence. Minute amounts of chloroform were obtained from the Japanese and Siamese, and carefully conserved for special procedures. I was able to obtain small quantities of "novocain" products, and this became the sheet anchor for spinal anaesthesia (1-2.5 ml. of freshly prepared 10% solution in distilled water). With variations of technique this sufficed for almost all opera-

tions on the abdomen and lower limb—e.g., gall-bladder surgery and amputations through the thigh. Local infiltration was much less economical but was necessary for the head or upper limb. Lieut.-Col. A. E. Coates did a most impressive series of 120 amputations of the lower limb at the 55-Kilo Hospital in Burma, employing a solution of cocaine (approximately 0.75 ml. of 2% solution intrathecally).

Catgut or other suture materials were rarely supplied by the Japanese, and numerous substitutes were used. I found cotton very useful, also silk obtained in quantity by unravelling the parachute cords carried by R.A.F. personnel. The most useful product was a locally prepared "catgut" from the peritoneum of pigs and cattle, first introduced by an ingenious Dutch chemist, Capt. von Boxtel, working under Lieut.-Col. Coates. The peritoneum was trimmed in 6-metre ribbons of varying width, twisted on a winder and dried. Sterilization was effected at 130° F. (54.4° C.) for half an hour, after which it was put in ether for twenty-four hours, and finally in 90% alcohol and iodine.

Surgical instruments were most scarce, and ingenious improvisations were made. On occasion razors and pocket-knives were used to make incisions, while butchers' saws and carpenters' tools found useful employment.

Surgery in Base Hospitals

In base hospitals the resources in tools, scraps of metal, and cherished oddments were greater, and some quite complex instruments were devised—for example, sigmoidoscopes, bowel clamps, rib shears, Cushing's silver clips and applying forceps, and optical apparatus. At Nakom Patom hospital, where the theatre was reasonably dust-proof and provided with a cement floor, a great range of surgical procedures were carried out under the enthusiastic direction of Lieut.-Col. Coates, who worked tirelessly at surgery in addition to administration. Major S. Krantz, A.A.M.C., has reviewed the surgical work of the hospital, in which he took an important part. Excluding very minor procedures, 773 surgical interventions were carried out, including such varied operations as brain and spinal-cord surgery, thyroidectomy, gastrectomy, enterectomy and anastomosis, abdomino-perineal resection, cholecystectomy, thoracic surgery, splenectomy, nephrectomy, laryngectomy, orthopaedic measures, and nerve sutures.

Appendicostomy, caecostomy, and ileostomy were allotted some place in the treatment of dysentery. Appendicectomy was carried out for appendicitis in 133 cases without mortality. Operations for hernia totalled 114, the majority being repaired with unabsorbable sutures. There were no deaths, 5 infected wounds, and 3 known recurrences. While it cannot be said that surgical procedures played a major part in the survival of prisoners of war, they represented considerable triumphs over unfavourable conditions.

Improvisation

Necessity is indeed the mother of invention, and while the Japanese were in the main obstructive rather than helpful they paid Allied prisoners the compliment of expecting miracles of improvisation to replace normal supplies. In heart-breaking jungle areas devoid of the most commonplace materials, where even pieces of wire, nails, fabrics, empty tins, leather, etc., were prized possessions, and habitations were made of bamboo and palm leaf held together with jungle fibre, ingenuity was indeed tested.

Astonishing uses were made of bamboo, which served for such varied construction as beds, brooms, brushes, baskets, containers, water-piping, tubing, splints, etc. Timber was obtained by felling trees and splitting with wooden wedges, and used for many purposes, including footwear (clogs). Where solder could not be extracted from sardine tins and the like, water-tight tin-smithing was done by ingenious folding. Sources of hydrochloric acid included the human stomach. Flux was readily manufactured if sulphuric acid could be stolen from car batteries. Leather was prepared from buffalo or cow hide, and thread or string from unravelling webbing equipment, kit-bags, etc. It was necessary to equip jungle hospitals by the work of patients as well as staff, and they were organized in mass-production efforts with all available tools and resources.

Articles made by this "cannibalization" of effects at Tarsau and Chungkai included urinals, bed-pans, commodes, surgical

beds and pulleys, feeding-cups, wash-basins, irrigators, sterilizers, small portable charcoal stoves, disinfectors, stretchers and stretcher beds (with sack and bamboo), back-rests, leg-rests, oil-lamps, brooms, brushes, trays, tables, orthopaedic appliances, splints, surgical instruments, and artificial limbs and eyes (from mah-jongg pieces). The artificial limbs made at Nakom Patom under the direction of Major F. A. Woods, A.I.F., were designed from crude timber, leather cured from hide, thread from unravelled packs, iron from retained portions of officers' stretchers, and oddments of sponge-rubber, elastic braces, etc.

Part of an appeal to camp members at Chungkai was: "The following articles are urgently needed: Tins and containers of all sorts, solder, flux, nails, wire, screws, sponge rubber, scraps of clothing, hose-tops and old socks, string, webbing, scraps of leather, rubber tubing, glass bottles of all sorts, glass tubing (transfusion purposes), canvas, elastic, rubber bands or strips, braces, wax, mah-jongg pieces, and tools of all sorts. Nothing is too old, nothing is too small."

Two Life-saving Achievements

A life-saving measure introduced by Major Reed, A.A.M.C., and developed by Capt. J. Markovitch, R.A.M.C., was the use of defibrinated blood for transfusion purposes. Using soldiers trained as technicians, thousands of transfusions were carried out by simply collecting the blood of a suitable donor into a container while stirring continuously with a spatula or whisk. Vigorous stirring was carried on for five minutes after clotting commenced on the spatula. The blood was then filtered through sixteen layers of gauze, and administered. Much help in the preparation of drugs and chemicals was given to medical officers by chemists, botanists, and scientists. Another life-saving achievement was the production of emetine from a limited quantity of *ipecacuanha* by Capt. van Bostel at the 55-Kilo Camp. Sgt. A. J. Kosterman and Sgt. G. W. Chapman did most valuable work in this respect.

Distilled water for intravenous use was prepared in numerous camps and hospitals. Alcohol for surgical and other purposes was obtained by the fermentation of rice with a suitable strain of fungus and distillation up to 90% strength. Grass extracts and other vitamin sources were exploited, and some useful items of *materia medica* were collected from local natural sources. From these, such products as essential oils—e.g., cloves and citronella—were obtained. Milk and bread made from soya bean lent some variety to the diet at times.

Products of minor importance included ink, paper, and cork substitutes. Major T. Marsden, R.A.M.C., provided an ingenious pathological service with improvised apparatus which satisfied most routine requirements. Colour indicators for pH were extracted from local flowers, and litmus paper was manufactured.

Conclusion

The treatment of sick prisoners by the Japanese left almost I civilized behaviour to be desired.

The fortitude and sustained morale of British soldiers under prolonged strain and suffering were most praiseworthy. The toll of long-continued strain and multiple debilitating diseases, merits consideration and sympathy in the problems of post-war rehabilitation.

The survival of many sick prisoners from the Far East was due to ingenious and devoted work by the various medical services, and to the co-operation, disciplined organization, and sacrifice of non-medical personnel.

Summary

1. An account is given of experiences in prisoner-of-war camps and hospitals in Java and Siam.
2. Disease problems and their treatment are briefly discussed.
3. Surgical procedures in remote areas and in prisoner-of-war hospitals are described.
4. A brief outline is given of the scope of measures of improvisation.

I am indebted to Gnr. J. Chalker, R.A., for the drawings reproduced on the special photogravure plate.

HAEMOGLOBIN AND PROTEIN LEVELS AND SPLEEN INDICES IN N. GREECE THEIR RELATION TO DIET

BY

HENRY FOY KALMAN RETTER
CHRISTOS DAMKAS MARGARET DEPANIAN
VALERIE MITCHELL AND R. J. PITCHFORD

(From the Wellecome Trust Research Laboratories, Medical Division of U.N.R.R.A., and Macedonia Malaria Centre)

The purpose of the present survey was to investigate the haemoglobin and protein levels in Macedonia and Thrace (N. Greece), to compare them with the distribution of malaria, and to discover any changes that had taken place since 1934 that might be regarded as due to the wartime diet of Greece or to the reputed low level of nutrition since the British occupation in October, 1944. In addition it was felt that some information was desirable on haemoglobin values in a part of Europe that is almost entirely agricultural or pastoral.

The results of the surveys carried out in Britain during the past eight years have tended to show that there is a relation between economic status, diet, and haemoglobin levels (Dobbs, Mackay, and Bingham, 1944; Mackay *et al.*, 1942, 1946; Davidson *et al.*, 1942, 1943, 1944; Fullerton *et al.*, 1944; Yudkin, 1944; M.R.C. Special Report Series, 1945; McCance *et al.*, 1938). Some authors (Davidson *et al.*, 1944; Fullerton *et al.*, 1944) have shown that there has been a slight rise in the haemoglobin levels during the war, which they have attributed to the wartime loaf of bread; this has, however, been criticized by Dobbs, Mackay, and Bingham (1944). A Belgian survey by Nizet (1945) states that there is no relation between malnutrition and haemoglobin levels. If malaria is present the haemoglobin picture will probably be further affected, but the relation of malaria to haemoglobin levels appears not to be a simple one, as is shown below.

In view of the British findings of a relation between economic status, diet, and haemoglobin levels it appeared important to ascertain what the situation was in a country that is admittedly at wretchedly low economic and nutritional levels (Fairley, Bromfield, Foy, and Kondi, 1938; Foy and Kondi, 1939).

The results of blood-protein assays in Britain showed values averaging 6.78 g. % in Canadian soldiers and 6.56 g. % in blood donors, with variations of ± 1 g. %, the figures thus being normal. Except in frank cases of starvation or semi-starvation, it is not to be expected that there would be any significant changes in the blood protein.

The relation of blood protein to the haemoglobin concentration has been fairly thoroughly investigated by a number of workers, and the conclusion drawn that there is very little correlation between them, falls in haemoglobin not being associated with similar or concomitant falls in blood proteins. In addition to the estimation of proteins, haemoglobin, and spleen index, a clinical and physical examination of school children for signs of malnutrition was included in the present survey as well as the results of tuberculin tests; the data for these will be published later by Dr. Kornbluh and Miss Rosenfeld.

Methods

For convenience the area of Macedonia and Thrace was divided into six regions, and in each region a number of villages, varying from 5 to 9, were investigated. The villages selected in each of the regions were chosen so as to give information regarding both mountain and plain villages, with a view to ascertaining any difference between them. The whole survey was carried out by the same team, and the haemoglobin and blood protein estimations were done by the same persons throughout the work. Thus unavoidable personal subjective errors inherent in the methods of haemoglobin estimation were eliminated or reduced to an absolute minimum—a point of the highest importance in haemoglobin estimations.

Proteins were estimated by the copper-sulphate specific gravity method (Phillips *et al.*, 1945).

Haemoglobin was estimated by two different methods—the direct Dare and the specific gravity. Hynes and Lehmann (1946) have shown the latter method to be very useful for mass

surveys. It must be admitted that even in the laboratory there is no really satisfactory method of estimating haemoglobin with great accuracy, with the possible exception of the gasometric. For choice in this laboratory the Pulfrich photometer or the Klett photo-electric apparatus has been used with alkaline haematin (Heilmeyer, 1933). It was impossible to use such methods in the primitive conditions under which this survey had to be conducted. The Haldane-Gowers carboxyhaemoglobin method was also impracticable, if only for the reason that neither the apparatus nor the carbon monoxide was available here. Recourse had therefore to be made to the Dare and specific gravity methods. It is fully realized that neither of these methods approaches in accuracy the spectrophotometric methods. More than ten years' experience of haemoglobin surveys in the primitive backwaters of the Balkans and Central Africa has, however, shown us that in experienced hands the Dare method is no more inaccurate than the Haldane-Gowers dilution method, especially when working at temperatures of 35° to 45° C. in the open country. The Dare and specific gravity methods were checked against the spectrophotometric alkaline haematin method of Heilmeyer, and the agreement in the great majority of cases was very good. It is felt, then, that the two methods used in the present survey, although leaving something to be desired, do give a fair and reasonable idea of the haemoglobin levels in this part of Europe. In our notation we have used grammes per cent, as being more in keeping with modern standards, and have taken the mean physiological normal as 15 g.%. The M.R.C. report used the percentage notation of the Haldane-Gowers scale, where 109.8% equals 15.15 g. % (Whitby and Britton, 1942).

The spleens were all palpated in the recumbent position, with the knees flexed, and the Hackett notation was used. This was the system adopted by the Rockefeller Foundation in its anti-malaria campaign, 1929 to 1937, and it has been used in Greece ever since, so that the spleen indices given in this report are comparable with all previous surveys. The blood was taken from the antecubital veins by wide-bore, dry-sterilized needles into tubes containing 2 mg. of dry potassium oxalate and 3 mg. of dry ammonium oxalate. The blood was withdrawn without any constriction whatever, and the specific gravity of whole blood was estimated immediately, and of plasma within from three to six hours after drawing the blood.

In all, some 1,500 protein estimations and 2,500 haemoglobin estimations have been made and 3,600 spleens examined. The cases in the various areas were selected at random from among the working inhabitants, and may fairly be said to represent a cross-section of the community.

The survey was done between the months of January and April, 1946, at a time when there is no malaria transmission, and before the relapse season has started. The spleen rates given are therefore to be regarded as minimal. It should be noted that the past four years have been ones of very low malarial endemicity in Greece, borne out by the spleen size distribution and the relation of the parasite index to the spleen index. In years of high endemicity or during epidemics the proportion of small spleens is high and the difference between the parasite and spleen indices much smaller. A further factor affecting the parasite index will, of course, be the taking of suppressive or curative drugs, of which mepacrine was given in large amounts during and since the war. The effect of these drugs on the spleen index will be much slower.

Protein Estimations

As will be seen from Tables I to VII and the Chart the proteins are within the normal range, in some cases above the

TABLE I.—Mean Haemoglobin and Protein Levels in the Six Regions

Regions	Haemoglobin, g. %				Protein, g. %				Spleen Index %
	Men	Women	Children	Total	Men	Women	Children	Total	
Florina ..	14.30	13.10	13.00	13.50	7.15	7.11	6.98	7.08	13
